Office of Principal Inspector General,
MEDICAL DEPARTMENT,
BANGALORE, 27*th August* 1862.

From ROBERT COLE, Esq.,
Principal Inspector General,
Medical Department.

To T. PYCROFT, Esq.,
Chief Secretary to Government,
Fort Saint George.

SIR,

In forwarding for submission to Government I have the honor to commend the accompanying *Report on the Causes of Death in Madras* for the year 1860, to the most favorable consideration of His Excellency in Council, as a production of unusual interest and value.

2. Mr. Cornish makes some observations on the advances made towards a more correct mortuary registration, and urges with great force and truth the desirableness of establishing a Census of the Population, without which sanitary statistics are comparatively valueless, which I earnestly recommend should be carried into effect.

3. From a consideration of the registered deaths of the Presidency, the numbers of which may be considered now to have been arrived at with some approach to exactitude, and comparing them with the more certain statistics of the Madras Native Army, two elements of which, numbers and rate of mortality, are exactly known, Mr. Cornish ingeniously deduces what appears to be a much more accurate estimate of the population of the Town of Madras, than what it has hitherto been considered to amount to; and 450,000, which the Municipal Commissioners also have calculated to be the amount, is considered to be a more probable number than the former mere guesses, which made it reach 700,000. This latter has

been for very many years put down popularly as the number of the population; and it surely offers a strong argument for registration being effected that so large a discrepancy as 250,000 should exist in the estimate formerly trusted to, and the more accurate deductions now made as to the numbers of people inhabiting the second city of our Indian Empire. By the same negative species of induction Mr. Cornish calculates the general death-rate of the native population of Southern India at 22 or 23 per thousand per annum. All these are approximations, but their discussion usefully serves to pave the way to a more perfect knowledge; and, by exhibiting how very far behind European countries we are, especially England, where there is a Public Officer to superintend, and an establishment ramifying all over the country, simple but effective, to carry out registration, a strong argument is adduced for extending to India the very beneficial and highly interesting inquiries, and I most respectfully urge the consideration thereof on His Excellency the Governor in Council.

4. The great bulk of Mr. Cornish's Report refers to the hygienic and sanitary condition of Madras, and the causes and sources of disease, and I cannot bestow too great praise upon his researches and observations; they are alike interesting to the practical physician and to the medical philosopher, and important to Government and to the Public. Nothing occurs to me to add thereto, and I concur generally in all his deductions and conclusions. I will only attempt to draw a practical corollary from the many interesting facts he has adduced, and the arguments he has grounded thereon.

5. Government are fully aware of the great need of measures being adopted to improve the sanitary condition of Madras. It has been the subject of anxious consideration year after year, and volumes have been written on different modes of cleansing the surface of the ground, of effecting a better drainage, and procuring a supply of water for drinking and ablution, and to flush the drains and sewers. There are Engineering difficulties which it is not my province to discuss, and financial obstacles, which I am not competent to judge of; but I may be pardoned for saying that the former, by British skill, may be surmounted, and that a money expenditure, whatever the amount may be, is not worthy of consideration, when put into the scale with the advantages to be obtained by the outlay.

6. It would be false reasoning to say that the rising generation will be no worse off than the present; that what has been submitted to so long

may well, under what seem, the insuperable difficulties of procuring a proper drainage and water supply, be allowed to remain; for, that, though the evils are acknowledged to be great, the future population will be no worse off than the present; and that the consequences after all have not been so very bad on the public health; for, on the whole, Madras is so salubrious a place, the "philosophy of stinks" rather goes to prove that such offensive odours are even conducive to health. This *laissez faire* policy will not suit such an occasion. It will not be simply the *status quo* under which the next generation will suffer. Year by year, decade after decade, the evil grows and multiplies. The loathsome drains become continually more soaked and saturated, giving out ever increasing foul exhalations. The pollution of the whole soil, from the bad drainage and the inadequate scavengering, goes on at an ever-increasing ratio; and we may look, as an inevitable consequence, for an increase of cholera and other zymotic diseases, at a rate proportionate to what we now actually see going on, with the constantly augmenting causes. The expression of a recent writer on Hygiene is not an hyperbole that, by a neglect of such measures, "an ultimate limit is set by the hand of man himself to dynasties, peoples, and nations." For, as he goes on to say, "the air we breathe, loaded with carbonaceous matter, sulphureous and sulphuric acid, sulphate of ammonia, and sulphuretted hydrogen, is deprived, by the absence of vegetation,* of the revivifying principle oxygen, and is hence less fitted for the necessary changes of the blood effected during respiration."

7. A very great misfortune for Madras and its population is, that owing to the levels and the configuration of the land, the sea itself, from which we draw our supply of purifying air is polluted by the discharge of sewage into it; for, except into the Cooum river and Cochrane's canal, no other exit can be found for it. No one can pass along the beach from the north-east angle of the Fort to the Custom House without being painfully sensible of this. I have myself been sickened by the inhalation of the foul gases emanating therefrom

* This, in Madras, would apply only to Black Town, but that is the most densely and numerously populated quarter.

I recommend that tree-planting be carried out as much as possible on the esplanade around Black Town, both for the shade afforded, and to give an agreeable aspect, as well as for the revivifying effect on the atmosphere mentioned by the author quoted. If any vacant spaces can be found, or created, in the midst of Black Town, it would add greatly to the salubrity of the place to clear and plant them with timber trees. The "People's Park" to the west of the town will no doubt contribute greatly to this salubrious effect.

merely in passing by, and have felt a nausea and headache for several hours afterwards, with a sensible flavour in my mouth of the mephitic gases inspired—this latter effect being, doubtless, not simply an impression produced on the lining membrane of the fauces by immediate contact with the foul air, but from an intermixture with the very circulating blood itself of the pestiferous exhalations, received into the lungs by inspiration. Now these gases may not, and rarely do, perhaps, contain the germs of cholera; but if, to their nauseating influences are superadded the morbific atoms, occult and hitherto undetected, of that or other zymotic disease, I need not say how much more obnoxious their baneful effects to individuals who respire them must be. The great sewer, which debouches into the sea at the north-east angle of the Fort, when the wind blows from that direction, poisons the surrounding atmosphere, on the contents being allowed to flow out during the night, which is the practice; and an Officer residing in the Fort informs me that, on this occurring, he is awoke from sleep, by the effect upon him of the foul exhalations.

8. Whether it is that the sea-breeze exercises its influence on the filthy waters of the Cooum, as stated by Mr. Cornish, by the abundance of *Ozone* which is known to exist in the air over the coast, thus actually decomposing and neutralizing its foul odors by chemical action; or whether, according to the simple popular notion, without resorting to chemistry for an explanation, the fresh wind dilutes and disperses the poisonous gases; it is essentially necessary that the breeze from the sea should reach the panting population in a pure state—But what is the case? From the Fort to Royapooram the wind, poisoned by the sewage flowing into the sea, blows back upon the inhabitants all the abominable gases in a concentrated form, which are incapable of neutralization by ten times the amount of *ozone* which may exist in the atmosphere. In any plan of sewerage, then, which may be adopted, it is absolutely essential in a sanitary point of view that there should be a main drain, at the lowest level a little way inland, for the Fort and Black Town, carried out north, as far as may be beyond Royapooram, debouching either into a back water, or into a reservoir, from which the contents might be conveyed and utilized as a manure. If the same could be done for the South of Madras, including Triplicane, Chintadrepettah, Royapettah, and St. Thome, the sewer might then be carried into the sea, a little north of the embouchure of the Adyar, without being a nuisance to any of the in-

habitants. Vepery and its neighbourhood might possibly—(I am speaking in ignorance of the exact levels)—be drained into the main sewer of Black Town, joining it to the north.

9. The Cooum, now a *cloaca maxima*, should have no drains terminate in it, and the above plan would preclude this. I earnestly plead, that this, heretofore most pestiferous body of water should have no impurities poured into it, and that endeavours should be made to keep it constantly full, by adoption of one of the several plans which are before Government. I most particularly urge this, for the sake of the General Hospital, the close proximity of which to its banks, is most prejudicial to its inmates; and I beg that Government will consider the large increase that will take place of the occupants of the institution, when the extensive additions now being made to the edifice are completed; on this subject, and on the means recommended for improving the banks of the gigantic cesspool called the Cooum, I beg to refer to my letter marginally noted.

No. 27, dated 10th February 1862, para. 4.

10. To flush the channels which are to convey the sewage to distant spots, along such a dead level as the plain of Madras presents, would require an enormous *vis a tergo*, and nothing but steam of considerable power would avail to effect it. I understand a project to raise sea-water by steam engines has been laid before Government; and the engine lately used in the erection of the Pier has been proposed for employment for this purpose. This might well serve to scour out the drains now terminating in the sea, and, as a temporary measure, would be of great use; but much greater power, and an infinitely larger body of water, would be necessary to urge forward the sewage, should it be determined to convey it northward instead of into the sea. Whether water is to be procured from the sea in this manner, or whether, by the grand project of Sir A. Cotton and Captain O'Connell, fresh water, stored by embankment of the Adyar and its feeders, is collected to provide Madras for all other purposes, as well as to flush the drains, I abstain from discussing as beyond my province and competence to determine. The great importance to the inhabitants of Madras of effecting the object by some method or other, I beg most earnestly to impress upon the notice of Government. I am perfectly aware that the abstract truth of the question is fully admitted, and that it is in fact a work of supererogation to urge upon Government the adop-

tion of measures, the necessity of which is acknowledged; but their adoption prevented or deferred by engineering and financial difficulties; but in presenting for the consideration of His Excellency the Governor in Council the present Report, showing the gradual increase of disease in Madras, and the continually augmenting sources thereof, I considered it incumbent on me to represent the necessity of taking steps to obviate what are indeed remediable causes of so much evil.

11. A plan for a more efficient system of scavengering, I have before submitted to Government,* and without some such means the pollution of the vast area over which the population of Madras is scattered must go on ever increasing The foulest contributions to the Scavengers' carts are the deposits from the dwellings in Black Town, Triplicane, &c., which are discharged into the open side-drains of the streets. These are indeed cesspools, for nothing but a torrent of rain (so rarely occurring at Madras) ever cleanses them thoroughly, and the porous, absorbent brick and chunam of which they are built, are sodden and saturated with the noisome matters allowed to flow into them, from the blackened gutters observed to pass out from every dwelling. Indeed these road-side cesspools, are used as *cloacæ* by the inhabitants, especially the juvenile portion, as may be seen, to the disgust of the beholder, in passing through the main thoroughfares which Europeans are in the habit of traversing. How much more must the practice prevail in the bye-streets! Cholera may now be considered as permanently *endemic* in Madras; and if, as is now believed, and as Mr. Cornish so forcibly represents, the germs of that dire disease are perpetuated and multiplied by the discharges from patients, which, under the circumstances I have stated, must every where infect the immediate neighbourhood of every human habitation, how can it be otherwise than that the pest will remain perpetually amongst us! It is within my recollection that the present deep masonry drains did not exist by the road side, and the evil decidedly was not so great as it is now. Then there was to each dwelling its own small offensive pool, which spread out, exposed fully to sun and atmosphere, and the fluid portion was evaporated and the solid matters were palpable, and swept up and carried away by the scavengers; but now, deep caverns exist, under the name of drains, which are indeed, as I have said, veritable cesspools, incapable of being thoroughly cleansed, in which the foulest matters lodge and fester and putrify. I would strongly recom-

No. 150, dated 26th Sept. 1861, and Pros. of the Madras Govt., Public Dept., No 1,481, of 1st Nov. 1861.

mend that the present drains be taken up, and others laid, built of slabs of the foliaceous granitic rock abundant near Madras, and "saucer" shaped, as I believe the Engineer's technical name is, that is, shallow and concave, wherein nothing can remain out of sight.

I have the honor to be,
Sir,
Your most obedient servant,

(Signed) ROBERT COLE,
Principal Inspector General,
Medical Department.

REPORT

ON THE

CAUSES OF DEATH IN MADRAS,

FOR THE YEAR 1860.

1. The number of deaths registered during the year was 13,498. The mean average of the previous five years was 9293·6, and the increase in 1860 above the former average 4,204. This increase has been due in some measure to the prevalence of Epidemic disease, especially cholera, diarrhœa and dysentery. But the whole of the increase is not attributable to these diseases. A considerable portion of it remains to be accounted for on the supposition that the total of deaths registered bear a truer proportion to the actual mortality than the returns of former years have done.

2. In the beginning of the year 1860, the system of publishing in the Fort Saint George Gazette a weekly table of mortality in the various Police Districts, was introduced.

In former years the Municipal Commissioners forwarded to the Principal Inspector General's Office only monthly returns of mortality for tabulation, and there were no means of ascertaining how far these were correct; but in January 1860 an arrangement was effected by which the Native servants of the Municipal Commission employed in collecting information from the various Burial grounds, brought in daily to the Principal Inspector General's Office, the death certificates of their respective Districts. This system, after considerable labor and exertion in overcoming obstacles in the way, was found to be an improvement on the former one.

The mortuary Conicopolies have some check kept over them as regards the registration of deaths amongst the Christian population, and the tables of these classes may now be accepted as nearly accurate. The deaths amongst Hindoos and Mahomedans, it is feared, are not yet so perfectly registered, although there is reason to hope that a considerable advance has been made in attaining greater accuracy than formerly obtained.

3. The publication of weekly tables of mortality has had the effect of directing attention to the unusual prevalence of diseases of an Epidemic nature, in particular districts, and the weekly Proceedings of the Municipal Commissioners show that the Native and European communities are awakening to a sense of the necessity of improving the sanitary state of the localities in which they reside. In this respect the weekly mortality bills have, it is considered, been already productive of much good.

4. One of the great difficulties in comparing the death-rate of the Presidency town, with that of any place the statistics of which are accurately known, is the impossibility of fixing the probable number of inhabitants, occupying the wide-spread and straggling Districts coming "within the limits of the Supreme Court" of Madras. The population has been variously estimated, and the estimates vary from 720,000 to 450,000. The Municipal Commissioners have lately attempted a rough census of the population through the agency of the Assessment Conicopolies, but the results it is understood are by no means to be relied on. Captain T. E. Bell, President of the Municipal Commission informs me that, in his opinion, the population of Madras has been much overestimated, and that there are good grounds for supposing the total of inhabitants to be not more than 450,000, if indeed there are so many. This view corresponds more with what we know of the ascertained yearly mortality, than the higher estimate of 720,000.

5. The registered deaths in Madras for instance, in the six years ending 1860, have averaged in round numbers 10,000 a year. Allowing another thousand to represent the unregistered mortality, and supposing the population to be 700,000, this would give a general death rate of only 15·7 per thousand—a rate lower than the mortality in the whole of England and Wales, which varies from about 36 per thousand in unhealthy towns, to less than 15 per thousand in healthy agricultural districts; and the general average of which is 22 and a fraction per thousand. But, on the other hand, supposing the population to be four and half lacs instead of seven, the death-rate estimated for the same period would be 24 per thousand, and considering the classes of disease which produce the greatest mortality, there is some reason for concluding that the latter rate is the most to be relied upon.

6. As a standard of comparison we may take the mortality of the Madras Native Army for a long period of years. The statistics of this body are sufficiently accurate to fix a mean death-rate of adult males at

what are spoken of as "Soldiers' ages." This death-rate is found to be, in round numbers, about 18 in the thousand. But it is enhanced above that of the corresponding portion of the Civil population by the vicissitudes of foreign or field service, and the prevalence of cholera when marching from station to station in the ordinary course of relief. It is affected moreover by the locality in which the soldier resides, some stations being peculiarly adapted for the preservation of health, while others (aided no doubt by other than climatic causes) have a contrary tendency. Thus, at the stations of Quilon, Jaulnah, and Bellary, it has been found that the death-rate of the Native Army does not exceed *seven* per thousand per annum; while in Burmah, the Straits, or China, the mortality has been so high as *twenty-nine*.

7. Now if the mortality in a body of picked men, between the ages of 18 and 50, amounts to 18 per thousand, or, excluding the number exposed to the greater wear and tear of life beyond the sea, to 12* per thousand, it is a fair inference that the general death rate of the Presidency, which includes persons of all ages, sex, caste, and occupation, must be more than 15 per thousand, or to express the same idea in other words, that the *estimated* population of seven lacs and twenty thousand, is much in excess of the *actual*.

8. We have some data for arriving at rough conclusions as to the general death-rate of the Native population of Southern India, although it does not permit of application to any one town or station.

The Registrar General of England shows that the mortality of the Civil population throughout England and Wales is 22·38 per thousand, and that the male population at Soldiers' ages, die at the rate of 12 per thousand, or much in proportion to what the Native Army loses by death in times of peace in its own country. If these proportions between the death rates of the army and Civil population are applicable to India as well as to Great Britain, and that they are so in a great measure there can be little question, we have, in the death-rate of the Native Army serving within the Presidency the means of calculating, although imperfectly, what the general mortality of the population must be.

---

* This rate is deduced from the average mortality for a period of ten years at twenty-three Stations of the Native Army in the Madras Presidency. The troops serving in Burmah, China or the Straits have been excluded in the calculation. This ratio in fact represents the mortality of the Native Troops in their own Country during peace only, and without including the casualties which occur in marching between station and station.

9. The calculation will probably be an under-estimate of the actual mortality inasmuch as the Native soldier in ordinary garrison-life (unlike the European) is placed in much more favorable conditions for the preservation of health than the bulk of the population at the same ages. In the first place he is a picked man, free from personal blemish or immediate tendency to disease, and is probably better fed, clothed, and lodged, than nine-tenths of his neighbours in civil life. His military duties (setting aside the occasional exposure and danger of marching or field service) are not ordinarily such as to injure his health, and in respect to his domestic residence within the "regimental lines" general cleanliness and order are enforced to a degree unknown in the ordinary Native villages or towns. He is, in addition, protected in some measure by vaccination from the dangers of small-pox, and enjoys the advantage of skilled medical aid whenever he may be incapacitated for duty by sickness. Under these circumstances, there is no reason to suppose that the death-rate of the Army is in excess of that of the male adult population; on the contrary, the small insight which the experience of the best of our Indian Jails gives as to the health of the poorer classes, would seem to show that it is much below the ordinary standard.

10. Putting all these considerations aside, and supposing the deaths amongst the male adults to bear a similar proportion here in India to what they are known to do in the entire population of England and Wales, we arrive at the conclusion that the annual ratio of 22 or 23 deaths to one thousand of living represents the general mortality for Natives of all classes in this Presidency. Although these figures represent only a very crude approximation to the actual death-rate (which can never be accurately known until a system of registration of Births and Deaths for the whole Presidency has been brought into operation) it would no doubt be seen that here, as in countries where statistical records of population are kept, the effects of condensation in towns, and the difficulty of providing those congregated in limited localities with the means of removing impurities, or supplying them with wholesome water and pure air, tell with marked effect in increasing sickness and mortality above the healthy standard which obtains in more scattered populations.

11. If we take the ratio in the foregoing paragraph as representing roughly the general mortality amongst the Native population in Southern India, we have an imperfect method of testing the correctness of the

mortuary returns of Madras, that is supposing the most recent estimate of the population at 450,000 can be in any degree relied on. Thus while the general average of the past six years shows, with imperfect registration, a death-rate of 24 per estimated thousand of the population, the year 1860, which as before stated was an unhealthy year, gives on the actual number of deaths registered a rate of 30 per thousand. These are however merely guesses at the truth, and it is not worth while to take up the attention of Government in speculations of this nature, except with the view of showing how much all progress as to the health statistics of the Presidency, must be at a stand still, until the bulk of the people have been enumerated, and the variations of the population by births and deaths are registered.

12. Madras has always had the reputation of being a healthy town, and there is no doubt that its death rate will bear a favorable comparison with those of Bombay or Calcutta, which for a given superficial area have denser populations. Death-rates usually increase in proportion to the density of population, and the Indian towns, so far as can be determined, are not exempted from the operations of this well ascertained law.

The mortality of the thickly populated districts of Black Town, Periamottoo, Triplicane, Chintadrepettah, will, as the result of that law, always be high, in comparison with districts which are more sparingly inhabited.

13. To revert more particularly to the causes of death in Madras during 1860, it may be mentioned that during the months of January February, and March, the population was singularly free from epidemic diseases. *Cholera* was almost entirely absent; only seven deaths being registered from that disease in the three months of the first quarter. *Small-pox*, which usually prevails with its greatest intensity in February and March, was not of frequent occurrence during this year. *Fevers*

---

* Assistant Surgeon F. Day, F. L. S., in his "Medical Topography of Cochin," Vol. 3, Madras Quarterly Journal of Medical Science, states that the yearly proportion of deaths to the population is 1 in 24, or at the rate of 41 per thousand. Cochin is one of the few places in India where any record is kept of the population or yearly mortality. According to Mr. Day, the natives are exposed to much sickness, and are short-lived in comparison with those on the Eastern side of the ghauts. The death-rate is certainly very high in comparison with that of Madras, or even of Bombay.

were, however, somewhat more prevalent than usual at this time, as were diarrhœa and dysentery. In the second Quarter of the year, and especially the latter two months of it, May and June, the mortality began to increase from cholera and dysentery. Of cholera, there were 6 deaths in April, 21 in May, and 88 in June. About the latter part of this month, it became generally prevalent. In the third Quarter, cholera attained its maximum, and in July the first month of the Quarter, it raged with great violence, destroying, according to the register 1,218 persons. In August there were 637, and September 276 deaths from cholera. During this period, the mortality was also high from fevers, dysentery and diarrhœa. In the fourth Quarter the decline of the Cholera Epidemic continued slowly, the deaths being 160, 91, and 76, respectively in the months of October, November, and December. Simultaneously with this decline in the cholera mortality, there was an increase in the number of deaths by fevers, diarrhœa, and dysentery.

The following table shows the monthly and seasonal variations in the mortality from five of the principal zymotic diseases for the year 1860.

Year.	Deaths from the undermentioned Diseases.	January.	February.	March.	April.	May.	June	July.	August.	September.	October.	November	December	Total
1860	Cholera..	3	2	2	6	21	88	1218	637	276	160	91	76	2,589
	Fevers	219	197	213	164	182	173	193	203	196	20	243	226	2,459
	Small-pox.. ..	7	22	30	25	35	30	13	16	23	13	9	22	245
	Diarrhœa	73	78	96	40	82	42	33	74	135	140	136	133	1,012
	Dysentery.. ..	76	68	86	85	109	103	124	159	104	133	139	113	1,326

14. The increase in the mortality from "Zymotic" diseases was influenced probably by seasonal peculiarities. From the end of December 1859 until June 8th 1860, no rain fell in Madras, and the quantity which fell in June, July, and August was just sufficient to moisten the surface filth and impurities of the town, without washing them away, while during these months the mean temperature was unusually high. It seems that rain fell on 7 days in June, 16 in July, 14 in August, and 15 in September, while the total rain fall in these months (the whole rain in fact of the South West monsoon) amounted only to 8·613 inches which distributed over the 54 days in which rain fell. gives an average of. 165 of an inch for each rainy day. The combination of heat and moisture, which obtained in these months, coupled with the irregular occurrence

of the purifying sea breeze,* and the general prevalence of land winds for the greater portion of the time, were causes in themselves most favorable to the development of miasmatic diseases, and must be duly taken into account in estimating the mortality for this period of the year. The truth of this observation is fully borne out from an examination of the meteorological returns of the period when the cholera mortality attained its maximum. On Friday the 20th of July 185 persons are reported to have died of cholera. From the 12th of July to the 20th the sea breeze blew only for a few hours in the evening of *two* days, the wind for the whole of the remaining period being W. or W. S. W., in the morning and W. N. W., in the evening. During this period rain fell daily in small quantities and the atmosphere was cloudy, close, and oppressive. The highest reading of the thermometer in this period was on the 18th July when it stood at 100·5° and the minimum 76·9. The day before the highest mortality occurred, the evaporation fell from ·496 to ·225 of an inch. The occurrence of a direct sea breeze, which blew for some hours on the evening of the 20th, was followed by a reduction in the mortality from 185 to 64 on the 21st, and from this period the daily deaths steadily declined, the South West wind and sea breezes prevailing during the remainder of the month.

15. The North East monsoon was likewise a partial failure. It began well in October, during which month 14·608 inches of rain fell, but in November and December there were only 1·445 inches. The total rain-fall for the entire year was only 24·6 inches or scarcely one half of the mean annual quantity registered in the last half century. It was only for a few days in October that the drains, and dirty localities

* The direction from which the sea-breeze comes is important, probably, in considering its purifying tendencies. Thus, I have noticed from actual observation that the violent agitation and exposure of the waters of the Coum River to the South, or "along shore" winds has the effect of rendering them *inodorous*. This fact was strongly brought to my notice a few weeks ago. While the winds continued to blow, until late in March, from the North East or North, the river was so offensive that it sickened many persons who had to pass it. Immediately the wind changed round to the South or South East the smell disappeared although the water was lower, and more fœtid mud exposed to sun and wind, than at an earlier part of the year. The most probable explanation seems to be that the agitation of the surface water by the strong south wind, brings into contact with the decaying matters of the river a large proportion of highly ozonized air which instantly oxidises or destroys the offensive matters. It is to be regretted that no observations are carried on at the Madras Observatory and immediately on the sea coast, as to the amount of ozone, in the prevailing winds.

in Madras, underwent a complete scouring, and the rain at other periods was never heavy enough to thoroughly cleanse the surface soil of accumulated filth.

The scanty rain-fall has otherwise been prejudicial to the public health of the district, in enhancing the cost of all the usual articles of food in demand by the native community. A good deal of scarcity and distress seems to have prevailed amongst the poorer classes.

16. The influence of seasons on the mortality from various diseases, and in determining the prevalence of those diseases, is perhaps better shown in a tropical climate than in a temperate one. In the annexed diagram (No. 1.) I have endeavoured to show what these seasonal variations are in Madras, as deduced from the Mortuary register for a period of seven years. This period is however too short to allow of the mean mortality of any particular month being accurately determined, and it is not at all improbable that the results of future years will render necessary some corrections in the wave line representing the seasonal mortality. The straight line A represents the actual deaths for seven years reduced to a monthly average. The wave line B the means of the different months for the same period.

17. A cursory examination of this diagram will show two well marked seasonal curves, one, the greater curve, embracing the months from January to September, and the other, the lesser curve, the period from September to January. The lowest portion of the greater curve occupies the space allotted to the month of June, and the lowest part of the smaller curve the month of November. These months are in fact, so far as can be ascertained, the healthiest of the hot and cold seasons respectively.

18. The great depression of the first curve opposite the hottest months of the year, April, May, and June, show them in the most unmistakable manner, to constitute the healthiest season in Madras. These are the months in which epidemic diseases are reduced to their minima, and in which the propagation of morbific germs giving rise thereto appears to be in a great measure held in abeyance. How far these actual results may have been influenced by the strong Southerly and Easterly winds, which prevail in these months, and which in a great measure reach Madras uncontaminated by noxious vapours arising from surface soil, is a question of very considerable interest. It cannot, however, be discussed with any satisfactory results, until the comparative amount of ozone in sea air and land winds, has been tested here by competent observers. Ozone, we have good grounds for believing to be Nature's own agent for preserving the

healthy balance of the gaseous constituents of the atmosphere. If it can be shown that the southerly winds and sea breeze contain more ozone than the winds from the north-west or south-west which blow over extensive tracts of land, the opinion is probably correct that Madras owes much of its immunity from epidemic disease during the hot months to the regularity with which these purifying breezes blow.* It will be observed that during the accession of the north-east monsoon, when the wind is pretty constantly a sea breeze, there is again a marked depression in the mortality and this fact would seem to give greater force to the conjecture above hazarded.

19. The diagram shows with equal distinctness, that the period of the year when the sea breezes are irregular or absent, and when the westerly land winds, or those due to the south-west monsoon prevail, the mortality attains its highest proportions. The combination of heat and moisture, which distinguishes the months of July, August, and September in Madras, appears to develope into activity the germs of cholera, dysentery, and diarrhœa, while the absence of the regular sea breeze to neutralize or dispel the noxious surface emanations, or to keep in check the tendency to decay or decomposition of all organic matters, allows these morbid materials to accumulate in favorable localities, and exercise their baneful influence unchecked. This is in fact the season of the year in which the tendency in all dead organic substances (and perhaps also in a restricted sense the living tissues of the human body also) to rapid decay is observed. The instances of this are familiar to every one. Fish caught in the afternoon, are stale in the evening—

The Western coast towns are generally freest from cholera, fevers, dysentery, &c., during the south-west monsoon, which on that coast is more or less, a pure sea breeze. The unhealthy months on that coast are those when the land or north-east winds prevail, or when the sea breeze is absent, or irregular. The periods of greatest sickness and mortality are exactly opposed to what we find on the eastern coast. In Bombay for a period of ten years the greatest mortality occurred in the month of April. It is in this month that the cholera mortality attains its greatest intensity while August is the month when the disease is the least fatal. The Linear Table of mortality for Bombay shows two well marked curves, one including the months from January to April of which February occupies the lowest place, and the other the months from April to January. In this diagram (No. 2) (which is copied from Dr. Leith's report for 1857) the mortality is seen to decrease gradually after the setting in of the south-west monsoon until October when it attains its minimum, and begins to rise again rapidly during the cold season

The comparison of the Bombay and Madras Linear Tables show how little temperature *per se* influences death-rate, and help to establish the law I have hinted at, that the more persistently a town or locality is exposed to a direct sea breeze in any portion of the year, the greater the immunity from cholera

meat bought in the bazaar in the morning becomes tainted if allowed to remain uncooked till the hour of dinner—fresh-water, if left to stand a few hours in a clean jug becomes stinking—while myriads of representatives of the insect world are called into existence and enjoy their brief hold of life, during this period of rapid change and tendency to decay. If the evidences of a general tendency to putrefaction are so familiar to us all at this season of the year, it will be the more readily understood in regard to all matters taken into the human body, whether it be the air breathed, the water drunk, or the food eaten, that if these essentials of man's existence be tainted, the living body will feel the effects of that taint in proportion to the feebleness or strength of the vitality of the individual. As Nature seems specially to have appointed the intestinal mucous membranes to the office of ridding the body of all decaying or fermenting matter introduced into it, by air, food, or drink, we have naturally at this particular season of the year a large amount of disease characterised by immoderate action of the bowels; whether the particular disease be cholera, dysentery, diarrhœa or typhoid fever, this general feature will be common to them all.

20. The progress of the cholera epidemic of 1860 deserves more than a casual notice in this report, not only from the fact that it caused one-fifth of the whole mortality in the town of Madras, but because the particular circumstances, general and local, which seemed to influence its progress, are deserving of careful study, and if considered in their true bearing, tend to throw light on the laws regulating the apparently capricious distribution of this and similar pestilential diseases.

21. There appears to be much confusion in the public mind as to the influence of foul odors from the filthy drains or river of this town, in producing out-breaks of cholera, and the subject properly comes in here for notice, as in the beginning of the year 1860, the nuisances alluded to were almost unbearable. So impressed were the principal inhabitants by the magnitude of the evil, that the "Sanitary Reform Committee" called a public meeting which was held in Patcheapah's Hall on the 26th April 1860, to discuss measures calculated to mitigate the effects of defective water supply and drainage; yet in the dry months when the effluvia from the drains were the most offensive to the senses viz. in January, February, March, April and May, *the town was singularly free from Cholera.*

It must be explained here that the cholera poison seems to have found a permanent resting place in Madras. In the seven years of which we have any record, there has been *no month* without a few fatal cases. Scarcely indeed a week has passed without a fatal case appearing in the returns, but in 1860 in the first *three months* of the year there were only 7 deaths put down to cholera, or on the average scarcely more than one fatal case in two weeks. This for Madras was a wonderful exemption and none the less remarkable that the offensiveness of the town in general was, at this particular period of the year, a matter of frequent comment in the leading columns of the local press.

22. There was another circumstance showing that smells and dirt *per se*, unless aided by certain climatic conditions, are not capable of generating or developing the poison of cholera in sufficient intensity to cause a general epidemic. In the month of March two troop-ships arrived from Calcutta with cholera on board. The men (one party of Europeans and the other natives) were landed and the European troops were quartered in Fort St. George and the Natives sent through to Vellore, yet with this provocation to an out-break (on the supposition that the germs of cholera find their allies in the drains and gutters, or the air which is poisoned by their emanations) no ill consequences followed, a mild case or two occurred amongst the men *from the ships*, but the disease did not spread.

23. A few isolated cases of cholera occurred in April, but in the last week of that month, and in the first week of May not a single death from this cause appears in the register. On the 6th May an Emigrant named "Mootoosawmy" died of cholera at the Emigration Depot in Choolay, and on the same day another case was brought to the Vepery Dispensary, though it is not clear whether he came from Choolay or not. However there can be but little hesitation in fixing upon this insalubrious locality as the spot where the tendency of the disease to become epidemic first showed itself. In the week ending 12th of May, out of a total of nine cholera deaths in the whole town, five occurred in and about this neighbourhood. In the succeeding week the cholera deaths were six, and three of these occurred in the 6th Police Division, viz. one in the original locality of Choolay, and the other two were the sons of a European pensioner residing in Pursewakum. In the third week of the epidemic the cases had dwindled to four, one of which occurred in the original locality of Choolay, and in the fifth week there was

one death from cholera in the whole town, a native "merchant" residing in Choolay.

24. Now in this brief summary of the progress of the epidemic in its earlier stages, we have conclusive evidence as to the manner in which it clung to one district of the town and in an inordinate degree, to a very limited portion of that district. We see that there was a tendency to the extinction of the disease, and we infer that this tendency was possibly influenced by favorable atmospheric conditions. It is worthy of remark that there were slight showers of rain on the 8th and 9th of June and again on the 17th, 19th, and 20th occurring after a very long period of drought and intense heat. These insignificant showers of rain (for the total did not exceed 1·573 inches) seem to have had the effect of re-awakening into life and activity the dormant cholera poison. For in the week inclusive of the 10th and 16th of June, there were 11 deaths, three in the 6th Division, three in Triplicane, and the others scattered over the town. In the next week the disease had caused 23 deaths, and these were spread over the whole of the police districts. From the 24th to 30th of June, the deaths had again doubled the number of the former week, and on the 26th of the month cholera again appeared (this time with more violence) amongst the coolies in the Emigration Depôt at Choolay. In the first week of July it became evident that an epidemic was amongst us, and one of no ordinary character; the deaths had risen from fifty in the last week of June, to 112, and although all parts of the town with the exception of the Fort suffered, it continued to press very heavily upon the districts included in the 6th Police Division, and especially those from whence the epidemic first sprung; out of the 112 deaths, 36 occurred in this 6th Division.

In the second week of July, the cholera mortality went up to 279—in the third week to 515, and in this period of time the disease attained its greatest height. In the fourth week the deaths had declined to 244. Throughout the first three weeks in August, the mortality steadily declined, but in the last week it rose again from 61 to 122, and from this time it fell, week by week, very gradually until the first week of January 1861, when only four cholera deaths appear in the register.

25. In a former paragraph it was attempted to be shown that the cholera first inclined to become epidemic in Choolay, a very dirty locality in the 6th Police Division of the town. The disease once being established began to spread rapidly in some of the other Police Divisions

and especially in the 3rd, 4th and 5th, which include Triplicane, Royapettah, St. Thome, Chintadrepettah, Egmore, and Nungumbaukum. In the third and fourth weeks of July, when the epidemic was at its height, the deaths from cholera in the Triplicane district exceeded those in the whole of the remaining portion of the town, and the mere mention of this fact shows how terribly the inhabitants of that crowded locality must have suffered in those few days. Fortunately the epidemic was swift in its career, if sharp. Had it continued for a few weeks with the virulence it showed in the third week of July, Triplicane would have been decimated of its inhabitants. The great disproportion in the mortality of Mahomedans began on the 14th of July, and continued until the 24th. In these 11 days the deaths amongst the Mahomedans were 342, and in the Hindoo population of the whole town only 317. In my report for 1859, I attempted to explain that judging by the registered deaths amongst each class of the community, the Hindoos and Parialis were probably six times as numerous as Mahomedans. It was also shewn that the latter class suffered unduly (from some undefined causes) in epidemic visitations of cholera. The experience of this year must have made it clearly evident to all that the Mahomedan community got more than their fair proportion of cholera. In fact for the short period in which the epidemic attained its maximum height the Mahomedans were being destroyed at the rate of more than 6 to 1 of the Hindoos and Parialis. The aggregate proportion for the whole year will be seen in the following table showing the proportion of cholera deaths, to the total mortality in each class of the community.

Proportion of Cholera, to total deaths.

Europeans.....	16 5	per cent.
East Indians.....	21.6	do.
Hindoos.....	17·6	do.
Mahomedans.....	25·9	do.

It will be observed that the Mahomedans and East Indians were the greatest sufferers from the cholera epidemic, and this is the more remarkable inasmuch as it prevailed severely in the great Hindoo quarter of "Black town" long after it had passed over Triplicane and the crowded parts of the 4th Police division.

26. From a conversation held about the time of the epidemic with an intelligent Mahomedan gentleman, I gathered that the mortality was something more alarming than the people had been accustomed to witness,

and that it was no uncommon thing for four, five, or more deaths to occur in a house. That in some instances whole families had been swept away in the course of a few days. The mortality was not confined entirely to the crowded district of Triplicane, for many respectable families occupying garden houses in Mylapoor, Thanampett, and other portions of the 4th Police division, suffered in an equal degree. The East Indian population of Chintadrepettah, Egmore, and Royapettah, suffered very severely. An employé in the Garrison Engineer's Timber depot lost 7 out of 12 relatives living in his house in 3 days, and similar instances were by no means uncommon amongst the poorer classes of the East Indian population.

27. The great mortality which occurred in particular houses, and amongst relatives having frequent personal intercourse on this occasion, has tended very much to strengthen the growing suspicion in the Native mind as to the contagious nature of the disease. As this feeling if generally concurred in would lead to neglect of the sick, and a morbid dread of encountering the invasions of the malady it is well perhaps to state, briefly and clearly, what the grounds are for supposing the disease to be communicable from person to person, and to point out how this risk of spreading the disease by personal intercourse is to be avoided.

28. The researches of all those eminent men who have considered the mode of propagation of cholera, go to prove that the peculiar poison which causes the disease is for the most part cast off from the body by vomiting and purging. That the discharges of cholera patients have the property of inducing symptoms of cholera if taken into the body in any way, has been proved experimentally by feeding dogs and other animals with these discharges, in various stages of decomposition, and the animals dying subsequently with symptoms analogous to those of cholera Now these discharges if thrown carelessly upon the ground sink into the soil, and under certain conditions of heat and moisture the cholera germs have a tendency to multiply with great rapidity; or if the discharges find their way into the drains, or if they be carried into the tanks or wells, either by percolation through the soil, or by the surface washings of stormy days, they retain in all these places their poisonous properties, and under favorable conditions, atmospheric and local, increase with marvellous rapidity. Some soils and waters are more favorable than others for the retention and increase of the cholera poison, and the deep alluvium of Madras, and impure water which percolates through it, appear to be too well suited to meet its peculiar requirements. What the exact nature of the poison may be, we have no satisfactory evidence to show, but with

the great advances which have been made of late years in pathological chemistry, and with the aid which the microscope gives to the observer of the present day, it is quite within the bounds of possibility that in a few years hence, the peculiar nature of this, and other allied poisons which exercise such wonderful effects on the human body, will admit of clear and precise definition.

29. Leaving this question for the present unsettled, it will be clear to the meanest comprehension that if the discharges from the stomach and bowels of cholera patients contain the elements of the disease, and if the air of the dwelling house, the water of the tank or well, or the food, be in any degree contaminated by these discharges, the persons breathing that air, drinking of that water, or partaking of that food, will be more liable to suffer the effects of such contamination than those who are placed in better hygienic conditions. In this sense only does cholera appear to be a contagious disease. It is not by any means so easily communicated as small-pox, scarlet-fever, or measles, and if a plentiful supply of fresh air in dwelling houses, pure water for drinking purposes, scrupulously clean and wholesome food, and personal cleanliness, were the rule of native communities, instead of the exception, cholera epidemics would lose much of the malignancy. which now unhappily characterises them.

30 Looking then upon cholera as a disease capable of being propagated by the morbid discharges from the bowels, it becomes a matter of great importance to know how the germs of the poison contained in those discharges can be destroyed, or rendered innocuous. There are several chemical agents which effectually destroy the contagious properties of the stools or vomited matters, such as chloride of lime, or zinc, Condy's disinfecting fluid, Carbolic acid; but none of these are available in daily life, besides which their cost would be an insuperable obstacle to their general use amongst the native population.

In practice, it is found, that if the discharges are received into vessels containing fresh burnt lime or dry powdered charcoal, simple substances within the reach of all, and the whole at once buried underground, the object is equally obtained. Dr. Mudge has tried the last named method in the Vepery Dispensary during two severe epidemics, and he states that since it has been adopted, no patient *in hospital*, nor any of the hospital attendants have been attacked by cholera; as a part of this system, the most scrupulous attention is paid to the cleanliness of the wards, cots, bed-clothes, &c. If any of these should be soiled by cholera discharges, the hospital attendants are instructed to remove them instantly

and apply a disinfectant before washing. The floors of the wards are invariably sprinkled with a disinfectant should they become soiled, and afterwards well scrubbed.

31. Dr. Blacklock, Physician to the General Hospital, informs me that so impressed is he with the contagious properties of the discharges from cholera patients, that he not only adopts all the precautions adverted to in paragraph 30, but directs the frequent removal of the perspiration which accumulates on the bodies of those in the collapsed stage of cholera, and has the surface of the body, from head to foot, sponged over with a weak solution of some disinfecting fluid. These instances are specially noticed to show the strong views which gentlemen of very great experience in the observation of cholera have been led to adopt, from witnessing the evil effects on the friends and relatives of the sick, or hospital attendants, where these simple precautionary measures are neglected. The practice of destroying the stools is not altogether new, and has had extensive trial by Dr. William Budd of Bristol, and other physicians of eminence at home, but it is not perhaps so generally adopted in the hospitals of this country, as it deserves, when cholera epidemics prevail.*

31. The remedy then for the prevention of the spread of cholera, should it attack a community, appears to be very much in the hands of the people themselves. The precautions are very simple, in fact too simple, for a people gifted with a capacity for the marvellous, to meet with popular acceptance. They may be all comprised in, strict personal cleanliness, temperance, wholesome drinking water, and food, abolition of cesspools and privies in private houses, daily removal of all filth and ordure from the neighbourhood of dwelling places, destruction of cholera discharges when cases occur, by quicklime and charcoal; purification of all soiled linen or clothes worn by cholera patients; and lastly, by paying attention to irregularities of the bowels, in seasons when cholera may be expected, and checking any tendency to looseness by the simple remedies which all are more or less acquainted with. These precautions, unless adopted by the whole population, will not prevent the occasional prevalence of cholera, but the disease would be shorn of many of its terrors, and we should probably hear less of those terrible instances of whole families being swept away in a few days, if they were generally attended to.

* Since this was written I observe that one of the most important of the recommendations of the "cholera commission" in the North-West Provinces promulgated by H. E. the Commander-in-Chief in India, in a G. O., is the destruction of the stools or discharges of cholera patients, as a means of preventing the spread of the disease.

32. The invasions of these epidemics, as instanced in the one now noticed, are often gradual enough to give some warning of their approach, and it is in the beginning of an outbreak only that human efforts can be made effectual in staying its progress. When a fire is once steadily burning and plenty of material at hand to feed upon, the efforts used to extinguish it are of no avail; it will burn itself out when there is nothing more within reach to destroy. The flames of the devouring element spread with scarcely greater rapidity than do the germs of cholera, when the conditions of atmosphere, humidity, and soil, are favorable to their increase. The "materies morbi" are easily destroyed when they occur in a limited space, as a newly-lit fire is readily extinguished; but if allowed to spread from house to house, street to street, village to village, become as unmanageable as the element with which they have been compared.

33. The public, and the Sanitarian too perhaps, are often inclined to place too much stress upon atmospheric or seasonal disturbances in connection with the prevalence or absence of epidemic disease. That these do have a very considerable effect in retarding or hastening the diffusion of certain diseases it is impossible to deny. The former portion of this report, for instance, bears evidence to the fact; but these effects appear to be only conditional on the elements of disease being actually present at the time in a given locality. The general atmospheric disturbance, or "epidemic constitution of the atmosphere," as some have called it, and of which so much has been said and written, appears to me of doubtful existence. If cholera originated in "a general disturbance of the atmosphere", or as a result of a disturbance in terrestrial magnetism, positive or negative electricity, sol-lunar influence, or any of the occult causes which have been hinted at by writers on the subject, we should not have the spectacle of the disease spreading with the greatest intensity for a week or two in Triplicane, then leaving that locality for Chintadrepettah, then a fixture for several weeks in Black Town, and lastly spreading with virulence at Saint Thomè. If the causes of Cholera Epidemics are exclusively to be found in general disturbances of the healthy condition of the atmosphere, why are the local effects so wholly dissimilar? The only logical conclusion seems to be that districts suffer in proportion to the intensity of the poison in their soil, water, or drains, and that this poison is essentially local in its development, aided only by general conditions of temperature, climate moisture, &c., in the same way that the growth of a seed of corn is aided, by these conditions being favourable, and the soil it is placed in, adapted for its support.

34. To illustrate how little the morbid matters of Cholera are carried by the atmosphere, we can scarcely take more remarkable instances than those which occurred in the course of the epidemic of 1860. Here the epidemic travelled slowly from East to West, always however along the high road of communication, and in the face of the South-west monsoon, or when the wind was entirely S. W. or W. In this manner it is proved to have reached Bangalore by the high road from Vellore. In several places to the South and South-West of Madras, the epidemic appeared several days or weeks later than in Madras itself, and in all these instances sufficient time elapsed to admit of personal communication of the disease along the great lines of traffic. In all the instances alluded to, the epidemic made its way against an opposing wind.

In the early part of 1860 an epidemic of Cholora in the Nagpore Provinces spread in various directions from a well ascertained nucleus, the nucleus in this instance being the camp of a large body of pilgrims assembled at a shrine near the caves of Mahaedo. Wherever these people fled to escape the pestilence (which their own dirt and crowding had created) they left a *Cholera trail* behind. North, South, East and West, the great highways of commerce, and cross country roads, remained so infested by the poison that they could not, for some weeks after, be passed without the greatest risk. The experiment was unavoidably tried by a portion of Sir G. C. Whitlock's Saugor Field Division coming, without foreknowledge, upon one of these Cholera tracks, and the result was an immediate outbreak of the disease amongst the troops, and the loss of many valuable lives. In this instance the disease was proved, not to have been wafted from place to place by the winds, but to have spread only in those localities which had been exposed to the sources of infection. The troops which were fortunate enough to avoid the high roads, although travelling in the same direction as others, did not suffer.

35. To come back more immediately to the history of the Cholera epidemic in Madras, there were not wanting curious instances of exemption, unaccountable on the supposition of a "general epidemic constitution of the atmosphere."

H. M.'s 43rd Regiment Light Infantry quartered in Fort St. George enjoyed almost a complete immunity from the disease, only one Soldier, and one Soldier's wife from the Parchery died of it. The fort from its situation, being clear of all surrounding buildings, and open to the sea, enjoyed many advantages over the more crowded streets of Black Town or Triplicane, but still considering that the troops were not placed under

any quarantine restrictions, and that hundreds of Clerks and others came into the fort daily from the Districts where the disease was raging, the exemption is not a little remarkable, and can only be attributed to the superior hygienic conditions enjoyed by those within the fort. The recent improvements in barrack accommodation, and the pure water supply from the seven wells,* must be considered as having tended very materially to the production of this very satisfactory state of things. It is worthy of remark, however, that two men of a detachment of H. M. 43rd Regiment L. I. which marched to Palaveram, were seized with cholera the next day and died; probably the exhaustion produced by the march rendered these men more liable to contract the disease on the road. There was no cholera at the time in Palaveram, but a few cases did occur subsequently to the death of these men of the 43rd Regiment.

36. The 4th Regiment N. I., with the families of the sepoys, occupied the lines of the late Sapper Battalion just outside the North of the town wall. There is nothing very particular about these lines, they being, in fact, simply mud huts, but they are regularly built, and the conservancy arrangements for carting away the house refuse and filth are more complete perhaps, than in streets within the town. Cholera prevailed for many weeks close to these lines in Black Town and Royapooram, and yet there was not a single case amongst the sepoys nor so far as I can learn among the women and children of the Regiment In the year 1861 which has just terminated this Corps and all the persons occupying that locality have enjoyed a similar immunity, notwithstanding the extreme virulence of the disease in the immediately surrounding neighbourhood.

37. If the facts I have now adduced go to establish the dependence of cholera more upon local than general causes, they no less tend to indicate the mode of investigation to be pursued in attempting to understand the laws which regulate the progress of this mysterious disease. If we find localities notoriously exempt—such for instance, as Honore on the Western coast, or the station of Palaveram near Madras, where, prior to 1860, no case of cholera was ever known to originate, or, during two epidemics, the still more limited space occupied by the Sap-

* I believe there are good reasons for concluding that the smaller mortality from cholera in Emigrants ships from Madras to the Mauritius is due to the very excellent quality of this water, which is used by the shipping generally. The Calcutta Emigrants it is understood derive their water supply from the river Hooghly, and the mortality from cholera is always high amongst them, when compared with that of Madras Emigrants.

per lines, near Royapooram, it is possible to compare all the local peculiarities of these limited spaces with those of districts which are annually visited by the epidemic, or which like Madras and Salem appear to be never free from it, and by noting the points of similarity or difference, to arrive at some definite conclusions as to the conditions which tend to the increase and multiplication, or the extinction of the germs of the disease.

38. Until this subject has been worked out systematically it seems scarcely requisite to summarise the knowledge we already possess regarding it, in a report of this nature. It may be sufficient to say that the mode of investigation here alluded to is being pursued by independent observers in different parts of this country, and that the results when generally known will tend to throw much light on the combination of causes which regulate the diffusion of this and other pestilential diseases.

39. It will be seen that the European community of Madras suffered nearly as much from cholera in the epidemic of 1860, as did the Hindoo population. That is 16·5 per cent. of the total of deaths in that class were due to it, and 17·6 per cent. amongst the Hindoo. A careful examination of the returns show that the Europeans residing in insalubrious localities were those most amenable to its influence. The "Sailor's Home, Stringer's street, Anderson's street, and New Town" were localities which contributed more than their fair proportion. Sixteen, or more than one-half of the total Cholera deaths amongst Europeans occurred in the 1st and 2nd Police divisions of Black Town. The classes most attacked were sailors, pensioners, and poor persons out of employ. Four or five deaths occurred amongst the higher classes of European society, and the great public loss of Sir H. C. Ward G.C.B., late Governor of Madras, is a memorable example of the fact that no official or social station gives exemption from this most formidable disease. His Excellency Sir H. Ward died on the 2nd August, a date when the epidemic was on the decline in the immediate neighbourhood of Government House. His Excellency appears to have been placed in most favorable conditions for the reception of the choleraic poison, residing within a few hundred yards of the districts of Triplicane and Chintadrepettah, where the epidemic raged so violently. A slight disorder of the bowels for some days prior to the fatal attack (thought to be due to the change of climate and residence, and consequently not

subjected to medical treatment) was the only evidence of the effect of surrounding influences upon His Excellency's health, until the invasion of symptoms characteristic of the severe form of cholera, and which speedily terminated in death.

40. The general tendency to disorder of the bowels, to cholera in fact in its milder form, prevailed throughout July and August in all classes of residents and caused much harassing labor to the Presidency Medical Staff. Amongst Europeans, medical aid was pretty generally sought for in this threatening of an invasion of the malady, and no doubt the small mortality amongst the well-to-do classes, is to be accounted for in some degree, by the early resort to appropriate remedies for checking diarrhœa. The various Hospitals and Dispensaries afforded relief to all applicants day and night while the epidemic lasted, and prepared medicines were placed in the hands of the Police at the several Tannahs for immediate use in all emergent cases. These measures no doubt checked the mortality in some degree, though, from the apathy and indifference of the natives in availing themselves of these opportunities, not to the full extent desired.

41. The influence exercised by careful attention to early symptoms of disordered bowels, by fresh air, and cleanliness, are perhaps most observable in examining the mortality from cholera of Children of tender years in the different classes of society. Thus, the numerous children of European parentage, who are for the most part well cared for, and enjoy more hygienic advantages than any other class of the community, have the lowest rate of mortality from cholera. Taking the total of cholera deaths in each class of the community and abstracting those of Children under five years of age, we find the proportions of the latter to the whole of the deaths of those at more advanced ages to stand thus:

Europeans.....	3·4 per cent.
East Indians.....	24·6 do.
Mahomedans.....	18·9 do.
Hindoos.....	11·2 do.

Here we again find evidences of the bad sanitary condition of the East Indian and Mahomedan population, of the former especially, in that their total of cholera deaths shows less than the proportion obtaining amongst Mahomedans, and yet the deaths of young Children from this cause are one-fourth in excess.

42. Cholera, however, is a disease which especially attacks and cuts off people in their youth and prime of life; about seven-twelfths of the whole mortality from this cause, occurs between the ages of fifteen and fifty-five, and nearly three-twelfths between the ages of five and fifteen. Young children up to the age of five years, and persons above sixty-five years of age, are the most exempt from it.

43. If this notice of the Cholera Epidemic of 1860, should be deemed somewhat prolix, I would plead in excuse that the consideration of the conditions which favor the presence of a pestilence destroying one year with another *one-fifth of those who die*, is a matter of the highest importance, not only to the Native community, but to those European Officials and others whose duties compel them to risk health and life, in residing within the limits of a town so liable to the disease. It is only by recording the mode of diffusion year by year, and the influences of season, or temperature, that we can arrive at a better knowledge of those laws which regulate the spread of epidemics. When pestilences are only occasional, striking down all in their progress, there is less opportunity for calmly considering their true nature, and consequently there has been and will continue to be, much conflicting evidence as to the causes influencing the mode of propagation of cholera, and arising solely from limited or defective observation of all the phenomena attendant on epidemic outbreaks.

It is too late to think of improving the site of Madras, but not too late to mitigate many of the evils resulting from neglect of those sanitary measures without which the very best natural advantages are rendered nugatory.

The measures calculated to improve the sanitary state of the town have been discussed so recently, and Government and the Municipal authorities are so alive to the importance of devising remedies to check its yearly increasing unhealthiness, that it seems scarcely necessary to go over the ground again on the present occasion.

44. The deaths classed under the order of Zymotic diseases have been in excess of the proportion of the year 1859. In the report for that year I showed that these diseases had occasioned about 50 per cent. or one-half of the whole mortality. In 1860 the proportion was 57 per cent., and of course much of this excess was attributable to the cholera epidemic. But there was also an increase in the deaths from fevers, measles, diarrhœa, and dysentery. Small-pox is the only important disease of this class in which there was any reduction of mortality in 1860, the deaths from it

No. 3.

MADRAS – SEVEN YEARS.

45. In the diagram (No. 1) given at a former page to illustrate the influences of season upon the general mortality for a period of seven years, it was shown that these influences were very considerable. To illustrate this more clearly, I have constructed two other diagrams, (Nos. 3 and 4) showing what these influences are upon the mortality from the more important Zymotic diseases, and a reference to them will show that it is the cholera mortality which gives the shape to the wave-line indicating the general mortality in each month. Seasonal changes have more influence in the spread of this disease and small-pox than over any of the other Zymotic diseases.

46. With regard to small-pox, it will be observed, that it attains its maximum height in the month of March, and this too with great regularity. In Bombay, Dr. Leith has found, taking ten years of registered deaths for a guide, that April is the most fatal month, and this gentleman has labored to show some evident connection between the

prevalence of small-pox at this period of the year and a magnetical disturbance attending "the passage of the earth through the point in its orbit, where the plane containing the sun's axes is perpendicular to the ecliptic," and when the poles of the sun are said to lean more towards the earth than at other periods.

According to Dr. Leith, "it is to this annual period that the small-pox mortality conforms itself." He further states that "the power retarding the prevalence of small-pox, is coincident in time with the earth's approach to the sun's pole in September."

The periodical increase in small-pox mortality is so regular both in Bombay and Madras, and probably throughout the tropics, that it is an interesting point of inquiry what influences determine this regularity. In Madras, *March* is the month of greatest mortality, and in Bombay *April*. Whether Dr. Leith's explanation holds good or not, it is evident that there must be some general law influencing the seasonal variations in the prevalence of this disease. Without the tropics it does not appear that this periodical increase and decrease has ever been observed.

47. The mortality from fevers in Madras appears to be less influenced by seasonal variations than from any other miasmatic disease. There is a slight increase in the cold season, or months of the North-east monsoon, and a decrease in the hot, dry months. Many of the deaths registered as "fever" are probably due to diseases which were unrecognised during life, and of which fever was the most prominent symptom to the unprofessional observer.

The fevers of Madras seem to belong more to the "continued" than the remittent or intermittent types; a form of low typhoid is not uncommon in some localities, and the worst cases of all types have a proneness to take on typhoid symptoms.

48. As the cholera mortality is seen to attain its greatest height in the hot moist months of July, August, and September, so the increase in the deaths by dysentery and diarrhœa follows closely upon the decline of the cholera. These diseases increase somewhat in October, November, December, and January, and as the hot dry months set in, they cause fewer deaths than at any other season of the year. In a population containing a large proportion of indifferently fed and badly-housed persons, these diseases are sure to be a source of constant mortality, and if the water supply be an impure one, the mortality will probably increase in a corresponding ratio in those localities which are badly provided with one of the most important necessaries of life. It is not improbable that those inha-

bitants of the Coromandel and Western Coasts who use badly salted and often semi-putrid fish as a common article of diet, suffer more than an inland population from these disorders.

49. The following table shows the proportions of the various classes of disease which caused the mortality in the whole population and in the several sections of it. A comparison of the figures in the various columns shows the differences in the liability of the various sections of the population to suffer from any given class of diseases. Thus for instance, "Zymotic diseases" which include cholera, fevers, small-pox, diarrhœa, and dysentery, are seen to cause 57·105 deaths out of every 100 in the whole town; but Europeans and East Indians in the year 1860 lost only at the rate of 44·571 and 44·827 per cent. respectively, from diseases of that class, while the Hindoos and Mahomedans died at the rate of 57·497 and 57·590.

Number.	Classes of Disease.	Per-centage of deaths to total mortality.				
		All classes.	Europeans.	East Indians.	Mahomedans.	Hindoos.

50. In the Report for 1859, I had occasion to remark on the great preponderance of deaths from "tubercular diseases," chiefly consumption, in East Indians. In the present year this preponderance has not

been observed, and to whatever causes it may be attributable, the registered mortality in that class of diseases has been lower than in other sections of the community. It is not improbable that some of the deaths due to Phthisis have been registered under another heading, Diseases of the "respiratory organs," from which class the mortality is seen to have been heaviest amongst East Indians.

It appears to be unsafe to make any general deductions on the liability of any class of persons to these diseases, until the yearly fluctuations can be corrected by the mean average of a series of years.

51. Diseases of the "organs of circulation" in the past year appear to have been most fatal to Europeans. Some of the great difference seen under this heading is perhaps to be explained from the fact that Europeans are always treated by Medical practitioners competent to diagnose these diseases during life, while the great bulk of the other classes do not enjoy such advantages, and the real cause of death in sudden and fatal cases of heart affection, amongst the natives especially, is not recognised, and consequently the deaths are registered under some other heading. These deaths are too few in proportion to the whole mortality to materially affect the accuracy of the tables of the more important classes of disease. There are no grounds for supposing that natives of the country are exempt from heart-disease, as the tables would appear to show. Violent and sudden bodily exertion, as in many of the athletic games and sports followed by Europeans, does appear to tend to the production of heart disease, or aneurism of the great vessels, and this is probably one cause amongst others why the proportion of deaths in Europeans exceed that of other classes whose habits are less active. Moderate indulgence in athletic sports does, no doubt, tend to preserve a healthy frame of body and mind. It is the abuse of these things which is here hinted at. There have been so many instances, not only in India but in other countries, where men, noted for their prowess in games, taxing to the utmost the physical strength, have died suddenly in the prime of life and vigor of manhood from the bursting of aneurisms of the large vessels or heart, that it seems right to mention these facts, in connection with the apparently large excess of deaths under this head amongst Europeans.

52. From diseases of the "Digestive organs" Europeans are seen to be the chief victims. Under this head is included all "diseases of the liver"

and these are well known to affect in a marked degree the European residents of tropical climates. In fact the great proportion of liver disease of the Europeans, explains the excess of mortality of that body under this heading. The causes tending to produce a degenerative inflammation of the liver in European residents of India are obscure. Diet has probably something to do with it. The use of too large a proportion of animal food, and of wine, spirits, and beer, probably tends to throw more work upon the liver than it can well bear, and thus excite it to take on diseased action. But the injudicious dietary arrangements of the European inhabitants does not account for the fact that in some of our Indian stations, diseases of the liver and particularly suppurative inflammation of the organ, are twice or three times as frequent as in others. The subject requires more careful investigation than has yet been given to it.

53. In noticing the deaths from "diseases of the Organs of Generation," which are made up principally of women dying in child-birth, it will be observed that the greatest proportion of deaths occur amongst East Indians and Natives. In 1859 three hundred women are registered as dying in child-birth, and in 1860 there were 346.

The proportions per cent. to the total female mortality in the two years are as follows:—

	1859.	1860.
Europeans	3·03	2·85
East Indians	5·35	4·75
Mahomedans	6·07	6·00
Hindoos	6·66	5·14

These figures do not vary much, except that child-birth seems to have been rather less fatal to Hindoo women in 1860. The age at which females of this country begin to bear children, has been a subject of much popular misrepresentation. If the register of deaths in child-birth is in any degree to be depended upon, the cases of precocious maternity must be very rare, for there is not a single casualty occurring to a female in child-birth at an age below fifteen years.

The mortality in fact of child-bearing women in this country conforms itself very much to what has been noticed in other countries, where the women marry at a later period of life. The ages at which the 346 casualties occurred were as follows, and the mortality from child-birth for one year in the city of London is added for comparison.

Ages.	*In Madras* 1860.		*London* 1853.
From 15 to 25	105	...	53
„ 25 to 35	159	...	138
„ 35 to 45	56	...	105
„ 45 to 50	6	...	4
Total.....	346	...	300

These figures go to show that as the greatest number of casualties occur between the ages of 25 and 35, this period is the one in which the greatest number of persons are exposed to the risk of dying in child-birth, or in other words that the period in question is the most fruitful to Indian women, as it is known to be to females living in temperate climates. The greater number of casualties in Madras between the ages of 15 and 25 is sufficiently explained by the fact of all Native women marrying at earlier ages than is customary in European countries. But notwithstanding these early marriages, child-bearing is more frequent between the ages of 25 and 35, tending to show that the reproductive powers are regulated by a physiological law applicable to the whole human race, viz. that these powers are most complete at the period when the vitality and physical strength are most perfect, and that the influences of climate in producing early maturity, or of early marriages on the fertility of a race, are much less important than have been commonly supposed.

54. There can be no question however that the mortality from child-birth is much in excess of what it ought to be in Madras. If only 300 women die in London, with its population of nearly two millions, then at the same rate there should be only 75 in Madras, that is, supposing the population of one city to be four times as large as that of the other. The excess of mortality in Madras is not a little remarkable, for the experience of the Lying-in-Hospital in many hundreds of difficult cases, shows that the mal-formations of the bony structures of the body, which in all large towns of Europe are a very common cause of danger to mother and child during the parturient process, are as a rule, never met with in native women. The latter die in fact not only from the accidents common to all women in their hour of peril, but in an inordinate degree from the ignorant and barbarous treatment which the uneducated midwives of the country subject them to.

If this great excess of mortality occurs in a town where there is a Hospital specially for the reception of lying-in-women, and which Institution does afford skilled aid to a thousand of them annually, it is

easy to understand that, in towns or districts where no such Hospital exists, the waste of life must be still greater.

55. Under Class XI, is included deaths from leprosy and elephantiasis, carbuncle, and other diseases affecting the integumentary portion of the body. No European died of diseases of this class; but the mortality amongst East Indians, principally from leprosy, is considerably above that of the Hindoos and Mahomedans.

Of leprosy, seventy-five males and thirty females died, the mortality being considerably in excess of the former year, when only sixty-one males and twenty females died of it. There seems to be no very satisfactory explanation, why this disease should be more than twice as fatal to males as to females.

There were nine deaths in the year recorded as due to elephantiasis, six males, three females. This disease appears to be very common, though not an immediate cause of death, amongst the lower classes of East Indians and Natives. Europeans do not suffer from it.

Carbuncle is also more fatal to males than females, sixty-one of the former and forty-seven of the latter are reported to have died from this cause. It is often connected with diabetes, and is essentially a disease affecting those of middle age or advanced life. The termination of Diabetes in Carbuncle is of very common occurrence in the better classes of natives, and especially in those Hindoo castes which abstain in some measure from animal food.

56. The proportion of "deaths from old age" under Class XV, appears to call for brief notice. The European population is one essentially of youth and middle age; the persons who stay to end their days in the country are too few in number to afford any reliable data as to the proportion of mortality which would obtain if all the European population was settled permanently in the country. It seems however from a comparison of the proportions amongst East Indians, Mahomedans, and Hindoos, that of the former 4·388 per cent. of deaths occur from old age, and of Hindoos 1·658 and of Mahomedans 0·722.

57. *Sex* appears to influence in some way the mortality at different ages. In the whole population it is found that the mortality of males exceeds, year by year, that of females. For every 100 females who die in a year there are 107·3 males. We have no means of ascertaining, on a large scale, the proportions of of the sexes born in this country but it seems that the law which holds good in Europe is equally applicable to India, that the births of boys should be in excess of

girls. The Registrar General of England shows that for every 100 girls born there are 105 boys, and judging from the death-rate of all the various classes of the community here, this is probably less than the proportion which obtains in Madras. In the Lying-in-Hospital at Madras in 1860 this proportion was considerably exceeded, for out of 937 children born 501 were males and 436 females. The proportion of males to females being at the rate of 114·6 of the former sex, to 100 of the latter.

The differences which have been observed in the proportion of the sexes born in various parts of England and Wales have never been satisfactorily explained. It is possible that the relative ages of parents have some influence in determining the sex of the children. In this country there is often great disparity in the parents' ages, the husband being always older than the wife in the Native population. It is not improbable that when this disparity is very great, the proportions of the sexes are materially influenced by it. The experience of the Lying-in-Hospital for the year 1860 is not a solitary* instance of the great excess of males born over females, for Dr. Paul in a valuable Statistical report on that Institution for two and a half years while he had charge of it, shows that the births of males were at the rate of 113 to every 100 females.

58. The male sex begin life under some undefined adverse circumstances. Even in coming into the world the proportion of boys "still born" is in excess of the girls. During the first five years of life they die at the rate of 72 per 1000 of living in England and Wales, while only 62 per 1000 of girls die in that period of life.

In Madras in 1860, the deaths of boys under five years of age amounted to 34·9 per cent. of the total male mortality, while the females of same ages died at the rate of only 29·05 per cent. Why this great disparity should exist in the mortality of young children of different sexes exposed to the same conditions of life is not all clearly understood. The regularity with which this excess appears, not only in our own returns but in those of European countries, would seem to indicate its dependence upon some general physiological law.

59. Through the next two quinquennial periods of life, from the ages of five to fifteen, the death-rate of the sexes is nearly equal, but from the ages of 15 to 35 the mortality of females is in excess. This is the period of life when the reproductive powers are in full sway, and in addition to the common ills of humanity, women suffer especially at this period from diseases and accidents incidental to the reproductive process, or functional or organic changes in the generative organs.

* Madras Quarterly Journal of Medical Science Vol. 1.

60. From the ages of 35 to 65 the deaths of the male population exceed considerably those of the female; why this should be is not very clear. In England the male mortality increases above that of women after the age of 45. The explanation is probably that men are more addicted to excesses in early life, and more wasteful of health and strength, and consequently fall victims at earlier ages to those diseases which are characterised by degeneration of the tissues of vital organs, such as the heart, lungs, kidneys, or nervous centres.

An examination of the general return of deaths of all classes according to age will show that the mortality from Phthisis, Diseases of the lungs generally, Digestive organs, Paralysis, is in excess in males at the ages specified.

61. Above the age of 65, the deaths of women are again in excess of the men, and the fair inference seems to be that a larger number of them live to attain that and more advanced ages. Of the persons reported to have died simply from old age (that is, all those deaths which may be regarded as due to natural decay of the powers of life) 53 were males and 157 females, the latter outnumbering the former in the proportion of 3 to 1. The proportions amongst East Indians are perhaps the most remarkable. Three men died from "old age" against 11 women, the rates in this instance being nearly 4 to 1.

The difference in the number of persons of the two sexes dying at advanced ages attracted my attention in compiling the Mortuary Report for 1859, and is alluded to in paragraph 41 of that report. The greater number of women living to old age and dying natural deaths, is not exceptional. The returns of all the years from 1855 to the present time, go to show that more than double the number of women die simply of old age than men. All statistics of age in this country must be cautiously received, but bearing this in mind it is difficult to account for the observed differences in the Mortuary Tables, (differences which are not of a variable or exceptional nature) unless on the supposition that the proportion of women living to a ripe old age is really much larger than in men. At the period of existence beyond that in which the special faculty of reproduction influences so materially the diseases and mortality of women, it is but fair to suppose that their longevity is due in some degree to the habits of early and middle life having been more strictly temperate in all things, and tending less to hasten that early exhaustion, or degenerative action of vital organs, which we know produces an excess of mortality in men about the age which should represent the prime or waning of life.

62. The class of "violent deaths" does not call for any particular

remark. They have been arranged on this occasion as *(a) accidental, (b) homicidal,* and *(c) suicidal.*

By far the greater number of them come under the first head; and accidental drowning in tanks, wells, or the sea, seems to have been fatal to fifty-two individuals.

There were four fatal cases of snake bite (cobra de capello), and one death resulted from the "bite of a rat."

The death of a child ten years of age is reported to have followed the sting of a scorpion. It is not often that injuries of this kind are fatal (although they are exceedingly painful) but a case occurred some years ago in the person of a young Officer where death was caused by a similar accident, and as this case was well authenticated, it shows that the poison of the scorpion may at times be sufficiently virulent to prove fatal.

Of suicidal deaths there were 16, and 15 of these were the result of drowning, and only one of hanging.

63. In the notice of the epidemic of cholera, the localties in which it specially prevailed were named. The following table has been constructed with the view of showing the proportions of each class of diseases causing mortality in each of the Police divisions and Sub-districts of Madras.

It includes the whole deaths amongst all classes of the population, and is chiefly interesting as showing the variations in diseases of the zymotic class in the various parts of the town; and it illustrates very clearly how much the mortality from these diseases is influenced by local circumstances. As shown before, the proportion of deaths from zymotic causes for the whole Town is 57 per cent. This table gives the variations in the different districts of the town. For instance, we find that in Perriamootoo 69·48 per cent. of the deaths were from zymotic disease. In St. Thomé 68·34; Royapettah 66·47; and besides these in the following places it was above the average—Triplicane, Alvarpettah, Meersaibpettah, Chintadrepettah, Coomaleeswarpooram, Egmore, Vepery, Choolay, Purse-walkum, Kilpauk, Perambore, Vaisarpady, Washermanspettah, Royapooram, and Cassemode.

64. The parts of the town which lost the smallest proportion of inhabitants from zymotic diseases, were Fort Saint George (25 per cent.); Uttapaleum (10·52); John Pereiras 36·84 Codumbaukum (17·64), Nungumbaukum (45·44) Mackay's Gardens (23·52), New Town (39·21) Gunpowder Mills (33·33); Tondiarpett (39·39.) In these last named districts the population is more widely scattered, and hence perhaps in some measure exemption from zymotic diseases of a fatal type.

PUBLIC DEPARTMENT.

PROCEEDINGS OF THE MADRAS GOVERNMENT.

Read the following letter from the Principal Inspector General, Medical Department.

(Here enter 27th August 1862, No. 72 A/159)

ORDER THEREON, 31st October 1862, No. 1,287.

With this letter the Principal Inspector General, Medical Department, submits, with his own remarks upon it, a Report on the causes of death in Madras for the year 1860.

2. This Report is ably drawn up, but the late date at which it is submitted must detract from its utility. There are, however, in it some points which deserve special notice, and these the Government will now proceed to consider.

3. The population of the Town of Madras has for many years been supposed to exceed 700,000, but recent inquiries on the part of the Municipal Commissioners have, it is stated, made it doubtful whether the number is as much as 450,000. Assuming this as the more correct estimate, the actual number of deaths registered in the year 1860, viz., 13,498, is at the rate of 30 per thousand, whereas the general average of the six years 1854 to 1860 was 24 per thousand, which, allowing for more imperfect registration in previous years, still tends to show that 1860 was an unhealthy year.

Report para. 4.

4. This must, however, be regarded only as a loose approximation in the absence of a reliable census, and the Municipal Commissioners will be asked to state what steps are being taken by them for obtaining a correct census of the population within their range.

5. From the table entered in para. 13 of the Report it appears that, of the five principal diseases there described, Cholera and Fevers were the chief causes of mortality; the former attaining its maximum during the third quarter, and its greatest intensity in the last month of that quarter, when it destroyed, according to the register, 1,218 persons; the latter, its greatest height in January, November and December, and that simultaneously with the decline of mortality from Cholera in the last quarter of the year, there was an increase in the number of deaths by Fevers, Diarrhœa and Dysentery.

6. To the small quantity of rain which fell during the months of June, July, August and September, and the general prevalence of land winds for the greater portion of the time, is apparently to be ascribed the unhealthiness of Madras during this period.

7. The Report further shows that the months of April, May and June, during which the southerly and easterly winds prevail, have been usually found to be the healthiest season in Madras.

8. On the questions of drainage and water-supply, to which the Principal Inspector General adverts, for the Town of Madras, the Government expressed themselves fully in their Proceedings of the 20th December last, No. 1,677, a copy of those Proceedings will now be sent to Mr. Cole. Reference will be made to the Department Public Works to ascertain what measures have been there taken on these questions. Nothing effectual can, however, be done until funds be provided. Application for an annual grant to the extent of a lac of Rupees was made to the Government of India, under date the 19th March last, but no reply has yet been received from that Government.

9. On the subjects treated in paras. 9 and 11 of Mr. Cole's letter, Orders were passed in the Proceedings of Government noted in the margin. The suggestion, however, at the close of that letter seems good, and the attention of the Municipal Commissioners will be called to it.

Dated 28th February and 8th March 1862, Nos. 272 and 305.

10. Mr. Cole's recommendation, contained in a note at foot of para. 6 of his letter in favor of planting trees in and about the Black Town, will also be referred to the Commissioners for their consideration.

(True Extract.)

(Signed) A. J. ARBUTHNOT,

Chief Secretary.

NOTE.

The system of Classification adopted in this Report and the accompanying Returns is similar to that in use in the British and Indian Armies, and in the Civil Medical Returns of the Madras Presidency. It was approved of and adopted at the Statistical Congress of Vienna in 1855 for the recording of diseases and mortality of all nations.

SYSTEM OF CLASSIFICATION.

I. MORBI ZYMOTICI—zymotic diseases.

Diseases that are either epidemic, endemic, or communicable; induced by some specific body, or by the want, or by the bad quality of food.

In this class are comprised the following Orders:—

1. Miasmatic diseases.
2. Enthetic diseases.
3. Dietic diseases.
4. Parasitic diseases.

II. MORBI CACHECTICI—constitutional diseases.

Sporadic diseases; affecting several organs in which new morbid products are often deposited; sometimes hereditary.

Order 1. Diathetic diseases.
2. Tubercular diseases.

III. MORBI MONORGANICI—local diseases.

Sporadic diseases; in which the functions of particular organs or systems are disturbed or obliterated, with or without inflammation; sometimes hereditary.

Order 1. Diseases of the nervous system.
2. ,, ,, circulatory system.
3. ,, ,, respiratory system.
4. ,, ,, digestive system.
5. ,, ,, urinary system.
6. ,, ,, reproductive system.
7. ,, ,, locomotive system.
8. ,, ,, integumentary system.

IV. MORBI METAMORPHICI—developmental diseases.

Special diseases; the incidental result of the formative, reproductive, and nutritive processes.

Order 1. Developmental diseases of children.
2. ,, ,, women.
3. ,, ,, old people.
4. diseases of nutrition.

V. VIOLENT DISEASES OR DEATHS.

Diseases which are the evident and direct results of physical or chemical force acting either by the will of the sufferer, or other persons, or accidentally.

Order 1. Accident.
2. Battle.
3. Homicide.
4. Suicide.
5. Execution.

REPORT

ON THE

CAUSES OF DEATH IN MADRAS,

FOR THE YEAR 1861.

In the year 1861 the total number of deaths registered was 13,370, of which number 6,974 were males and 6,396 females. The cause of death was specified in 13,362 instances, leaving only the small number of 8 to which no cause could be assigned. It is not intended by this remark to be inferred that the true cause of death has been given in every case, but the fact of so few deaths being registered without naming a disease proves that the Register is now so far complete that no names are admitted into it without due enquiry.

2. It will be observed that the mortality during 1861 has been very high, though slightly below that of 1860. The deaths for the former six years are entered in the margin by way of comparison. The causes of the great increase of mortality during the two latter years are probably twofold. Something is to be attributed to the greater precision and correctness of the registration, and secondly, miasmatic diseases have been more rife than usual amongst certain sections of the population and in certain districts of the town.

1855	10,627.
1856	8,453.
1857	6,968.
1858	10,148.
1859	10,292.
1860	13,498.
1861	13,370.

3. The year 1860, as observed in the report for that year, was marked by great drought and prolonged high temperature, and almost complete failure of the monsoon rains. The year 1861 was somewhat better off in these respects, but still the total rain-fall was lower than usual, there being only 36·303 inches instead of 51 inches, which is the average rain-fall in Madras. Rain fell on 73 days in the year, and the only months in which there was no rain were January, February, and April. The heaviest rain fell in August,

September, and November ; in the two former months it came from the South West Monsoon, and in the latter from the North East.

The average temperature of the air was slightly lower in 1861 than in 1860, and the hot season less trying and oppressive. The atmospheric conditions which favor epidemics of Sunstroke or insolation were not once present in Madras during the hot season. Thunder-storms were not infrequent during the rainy season, but no violent atmospherical disturbance occurred. In the month of May a remarkable dust-storm passed over Madras from the North West, with lightning and thunder and followed by heavy rain.

4. The commencement of the year was noticeable for the high prices of food, and for a great deal of privation amongst the lower orders. These circumstances however were not peculiar to Madras, but obtained pretty generally over the country.

5. As usual, the most unhealthy months were included in the period from July to October. Cholera attained its maximum height in September. This disease was more fatal even than in 1860, but more equally distributed throughout the year. In all 2,776 deaths were registered from Cholera against 2,580 in 1860.

6. The beginning of the year saw the town pretty free from Cholera. Early in February the disease broke out in an epidemic form amongst the coolies detained in the emigration depôt at Royapettah. The bad sanitary condition of the place was brought to the notice of Government in letter as per margin, and the depôt was subsequently removed to a more convenient locality.

No. 26 of 16th February 1861.

7. This outbreak is noticeable inasmuch as it appeared, from enquiries conducted at the time, to be clearly traceable to fœcal poisoning. Upwards of 400 persons were confined in huts which could not properly accommodate half the number. No privy or latrine was provided in the field, and the entire surface of the ground was found by the District Medical Officer sodden with human excrement. In the inquiry which followed upon the outbreak of Cholera, the Municipal Inspector and Police Peons stated that they had failed to perceive any noxious odour from this place ; but against this testimony I can state from personal knowledge that the road alongside the depôt was literally poisoned by the horrible odour proceeding from the depôt for some days before the Cholera broke out, and the Deputy Inspector General of Hospitals, Presidency, who visited the spot while it was undergoing a

cleansing after the dispersion of the coolies, stated that the nuisance was most overpowering and sickening in its effects.

8. The real evil of overcrowding, as in the Royapettah depôt, seems to be the concentration of human filth, which cannot accumulate beyond a certain limit without producing epidemic disease. Wherever natives congregate, whether it be in Military camps, at famous shrines for pilgrims, in crowded towns, or in the huddled together mud huts of isolated villages, the atmosphere and soil are sure to receive a fœcal taint, and to become *foci* for epidemic diseases, and more especially Cholera. The evil is increasing year by year, and must continue to increase so long as the present imperfect arrangements for the carting away of night-soil from populous districts are in force.

It is not too much to say that Cholera is almost, if not entirely, kept up by the filthy habits of the native population, who whenever they have the opportunity use the road sides and hedge rows and waste places, as open necessaries. There is scarcely a village or hamlet in the country the air of which is not vitiated by the emanations resulting from this abominable practice. The system is so deeply rooted amongst the people that nothing but the strong arm of the law can be brought to bear upon it, with the view of mitigating the evil, and of diminishing the sources of Cholera.

9. Epidemic Cholera it must be remembered, is essentially an Indian disease, born, bred, and fostered in the congenial dirt of Indian towns and villages, these being nearly always notorious for their fœcal atmosphere. Only within the last few months reports have been rife regarding a *new* and very fatal form of disease, (apparently a compound of Cholera and Typhus Fever), which is said to have appeared in the neighbourhood of Calcutta, and to be destroying thousands of the population. The appearance of a new form of disease is not to be wondered at, considering the utter disregard on the part of native communities to the teachings of sanitary science. We must expect Cholera and epidemic Fever to be either constantly or occasionally amongst us so long as heaps of human ordure are allowed to pollute the soil of dwelling places and the atmosphere we breathe. If this subject is dwelt upon somewhat forcibly, it is that the evil cannot be too widely discussed with the view of stirring up those most interested in its suppression to a sense of its enormity, and to consider it in its personal bearings as a question of health and long life, against disease and premature death.

10. The great mortality from Cholera in a family residing in Menand's

No. 1213 of 22nd August 1861, Public Department.
No. 1278 of 5th September 1861, Public Department.
No. 1481 of 1st November 1861, Public Department.

Lane, Pursewalkum, in the month of August, attracted the attention of Government, and the subject was specially reported upon in Proceedings of Government as per margin. Here again filth, and an atmosphere tainted by a rubbish depôt appear to have produced the usual results.

It has been argued that because the sweeping and rubbish of the town when used for street making and raising the levels of swampy places, are covered over by soil or metal, that it ceases to be injurious to the public health. The argument however will not bear a moment's investigation. If the filth is spread out in a thin layer and ploughed into the soil, the latter deodorises the former, and appropriates to itself all that is necessary to ensure fertility and a productive crop of vegetation. Used in such a way all decaying organic matter is got rid of with the least injury to health and life of human beings. But when it is covered up in a large quantity, the deodorising and disinfecting power of the thin layer of superimposed soil is unequal to the task it is expected to perform, and consequently the surrounding soil and water supply become surcharged with organic matter of a prejudicial character. If houses or huts are erected on such sites, the surface emanations are destructive to health. Cholera, and virulent Fevers, at one time or another, are pretty sure to seize upon the inhabitants of such localities and destroy them.

11. The mode in which natives occupy a new locality and hut themselves within the limits of the town appears to be objectionable, considering the sanitary bearings of the question. The process is generally somewhat as follows. A piece of ground being let out or sold for building sites, large excavations are made wherewith to run up the mud walls of the huts. These excavations are gradually filled up with house rubbish, and filth of every kind, and so the soil and water supply in the immediate neighbourhood at once become polluted and the site becomes irremedially surcharged with organic matters, which fester and putrify under the influence of moisture and heat, and become a standing nuisance. A piece of ground just north west of Pater's Gardens has lately been built over in the manner described.

12. The Municipal Authorities by Act XIV of 1856, Sections 22 and 23, appear to have the power to insist upon the laying out of new streets and buildings, so that drainage and ventilation shall be practicable, but it is a power which appears to be rarely if at all used. I would beg to point for

instance to the native buildings on the Mount Road near the "Thousand Lights" to show, that there is no systematic supervision of the construction of such buildings, that the basement of native dwellings is scarcely raised above the level of the surrounding soil, whereby efficient drainage becomes impracticable. Every man builds his house in the position and shape which seems best in his own eyes. The evils in a sanitary point of view of this independent action on the part of owners of house property must be sufficiently obvious to all who think of the matter.

The Municipal Act further empowers the Commissioners to punish by fine all instances of neglect to remove filth (Sections 40 and 41) from houses or grounds, when such may be offensive or injurious to health, but the machinery for carrying out this authority would appear to be defective. It always must be so until health Inspectors are appointed, and armed with authority to inspect the *interior* of Native dwellings. It is impossible to certify to the cleanliness of any native house from a simple observation of its exterior, while the elements of disease and death may be rife within, but studiously concealed from view.

13. These remarks apply especially to the prevention of Cholera, a disease which for many years past has been fearfully destructive of life in the city of Madras. With the example before us of what has been done in the way of *keeping out* Cholera from the European Barracks in the Fort, since 1859, there need be no hesitation in trying to accomplish a similar work for the denser parts of the town. The example is sufficiently encouraging to warrant any reasonable expenditure having for its objects a pure water supply and improved drainage, plenty of fresh air in streets and houses, and simple and efficient means for keeping the town free from fœcal filth.

14. As in the epidemic of 1860, the peculiarity of the Cholera mortality keeping almost exclusively to certain localities, the epidemic shifting only slowly from place to place, was well exemplified. Singularly enough, the Triplicane and Royapettah Districts, which suffered so severely in 1860, were the most exempted in 1861.

The great force of the disease was expended in Black Town, Royapooram, Pursewakum, and Vepery. In the locality of Peddoonaik's pettah, for instance, there were 1,008 deaths from Cholera in 1861, while in 1860 there were only 575. In Triplicane on the other hand there were only 124 Cholera deaths in 1861 against 583 in 1860. The causes of these variations are not easily accounted for. Both Triplicane and Peddoonaik's pettah are

very crowded localities, very dirty and ill drained, badly supplied with drinking water, the streets and houses ill ventilated, and both localities apparently equally suitable as Cholera *foci*. With regard to Triplicane however it is not to be forgotten that in the year 1861 the beginning of the improvements about the grounds of the Chepauk Palace must have had some effect in admitting a free supply of fresh air to the dense population. The overgrown grave yards and private burial places had in a great measure ceased to be obnoxious to the public health, and possibly, from the large number of victims in 1860, the number of persons susceptible to the Choleraic poison in the following year might have been considerably lessened.

This diminished susceptibility after the prevalence of severe epidemics has been observed with regard to Small Pox, and Fevers, and it is just possible that the same law may hold good with respect to Cholera, and that explanation may be the proper one to account for the marked diminution in the Cholera mortality of Triplicane during 1861.

As usual in Cholera Epidemics the European victims were mostly those residing in dirty and ill ventilated localities; 23 Europeans died of Cholera during the year, and 11 of these were, at the time of attack, residents in the Black Town district. No death from this cause occurred amongst the European troops in the Fort Barracks, and the large number of European residents in the 3rd, 4th, and 5th Police Divisions, were almost entirely exempted from the epidemic.

15. Besides the heavy mortality from Cholera the deaths were more numerous than usual from Small Pox. There were 655 deaths registered as due to this disease. Small Pox was very prevalent in Bombay in 1861, causing about 1,600 deaths, and many other parts of the peninsula of India suffered also from this epidemic malady.

16. The deaths from Fevers were less in number than in 1860, the numbers being as per margin* in each year. Measles were more prevalent and fatal in 1861 than in any of the years since registration has been practised.

1860	2,399
1861	2,169

With regard to other diseases of miasmatic origin, there has not been much variation in the past year to call for special remark.

17. The numbers of the various classes of inhabitants dying in the

last three years are given below, with the view of showing the influences of the unfavourable seasons of the two last years on public health.

	1859	1860	1861
Europeans.	122	175	154
East Indians.	224	319	400
Hindoos.	8,120	10,790	10,870
Mahomedans.	1,826	2,214	1,946

It will be observed that the East Indian and Hindoo Communities lost more than the average in 1861. That the deaths of Europeans have been less in 1861 than in 1860, though in excess of the number occurring in 1859, and that the Mahomedan deaths have been fewer in 1861 than in 1860, and this probably in a great measure from the comparative immunity from Cholera during 1861 of Triplicane, the principal Mussulman locality in the town.

18. Of the 154 deaths occurring amongst Europeans in Madras, 81, or rather more than one-half, were of persons actually or formerly in Military employment, and their families. The mortality of the Troops in the Fort during this period was singularly small, not more than 5 per thousand of strength, and had the same death ratio prevailed in the European community outside the Fort, there can be no doubt that the total number above given would have been most materially lowered. But the Troops in the Fort, at least such of them as occupy the barracks, now enjoy many advantages in a sanitary point of view over the lower classes of Europeans, who reside in the Town, and are exposed to its mephitic exhalations, and hence the smaller losses by death. The number of Europeans residing in Madras it is impossible to estimate without a regular census; but if this were obtained, the superior healthiness of the Troops in the Fort, over the residents in Black Town, Vepery, &c., could be very easily demonstrated.

19. Death appears to have been very busy amongst the East Indian people during 1861. Of the 400 casualties amongst this class of the population, 86 or 21·5 per cent were due to Epidemic Cholera. This is a high proportion as will be observed in the following comparison of

Proportion of Cholera deaths to total mortality.

Europeans	14·9	per cent.
East Indians	21·5	do.
Hindoos	22·1	do.
Mahomedans	13·3	do.

and almost equal to the mortality of the Hindoos, whose most populous districts were severely ravaged by the Epidemic in 1861.

20. Under the heading "Diseases of the nervous system," will be found an enormously large proportion of deaths of young children from convulsive disorders. A child dies more or less suddenly in a fit, accompanied by muscular twitchings of the body, and the death is registered as "convulsions," although the exact predisposing cause or causes of the attack is unknown. In 1861 there were not fewer than 812 deaths of babies, mostly under 12 months of age, from these convulsive affections. It has been conclusively shown that the children brought up in crowded towns where the air is foul, the houses small, and badly ventilated, suffer more in proportion from these disorders than do those inhabiting rural districts. Foul air, overcrowding, and filth, kill tender infants, it would appear, through the operation of their poisonous influences upon the brain and nerves. The foul exhalations from sewers and drains, which produce in strong and healthy men headache, sickness, and languor, seems to be more hurtful to tender infants, inducing sooner or later in the weaker of them convulsions, coma, and death.

In the past three years the deaths of young infants from convulsions have been steadily increasing as shown in the margin, and it is worthy of remark that the increase has kept pace with the filthy condition of the town during the two last years in which the scanty rain-fall was inadequate to cleanse the surface, or to scour the ill-constructed drains of populous districts.

1859	526.
1860	706.
1861	812.

21. The deaths from violence do not call for any particular remark. It is not a little remarkable, however, that not a single case of "poisoning" appears in the Register for 1861. We know that deadly poisons abound in every bazaar, that there is no check upon their sale, and that the people are familiar with the use of arsenic, corrosive sublimate, nux vomica, aconite, opium, stramonium &c., and yet with all these deadly agents ready at hand for homicidal or suicidal purposes, no instance of death occurring from the administration of poison, has been recorded.

To explain this curious fact we must suppose that the inhabitants of Madras have a smaller proportion of criminals amongst them than most other towns, or that in this seemingly moral and peaceably disposed population, there is an under current of crime which escapes the vigilance of the police authorities.

As stated in a former report, in allusion to this subject the symptoms of irritant poisoning are to the ignorant native not unlike some of the more common forms of mortal disease, and hence perhaps the reason why so few cases of criminal administration of poison come to light in law-courts.

Cases of poisoning, or of suspected poisoning, appear from the Chemical Examiner's experience to be much more frequent in the Mofussil than in the Presidency town.

22. In the tables accompanying this report, a slight change has been effected in the classification of the causes of death to assimilate both nomenclature and classification with that now adopted in the British Army, and Civil Medical Records of this Presidency.

W. R. CORNISH,

Assistant Surgeon.

5th December 1862.

PUBLIC DEPARTMENT.

PROCEEDINGS OF THE MADRAS GOVERNMENT.

Read the following Report on the causes of death in Madras for the year 1861.

(Here enter 5th December 1862.)

ORDER THEREON, 4th July 1863, No. 780.

The Government remark with pleasure the steady progress towards efficient Registration evinced by the statements submitted with Dr. Cornish's Annual Reports. They agree with him in thinking that the fact of the causes of death not being specified in only eight cases out of 13,370 deaths in 1861, may be taken as fair evidence that no names are now admitted without due inquiry.

2. The number and nature of the deaths themselves do not appear to call for any special remark. The mortality was slightly below that of 1860, but was high in comparison with former years; the large number of deaths registered being attributable partly to the increased correctness of the returns, but mainly to the prevalence at some seasons of 1861, of Cholera and Small-pox with unusual virulence. There were, moreover, no less than 812 deaths of infants registered as from convulsions and convulsive disorders, which Dr. Cornish seems to consider to be also attributable rather to miasmatic diseases brought on by overcrowding and bad air.

3. With reference to paragraphs 6 to 13 of the report which contain Dr. Cornish's remarks and suggestions on the subject of sanitary improvements, the Government observe that the question has long engaged their anxious attention, as is shown in part by the Proceedings he quotes. The plans for carrying out these improvements are still under the consideration of the Government.

4. The attention of the Municipal Commissioners will be drawn to the suggestion made in the first part of paragraph 12, which seems one that may easily be carried out and is likely to have good effect; but the Government are not prepared to sanction Dr. Cornish's proposal to authorize the inspection for sanitary purposes of the interior of private dwellings.

5. The occupants of houses who by any act or omission create or allow to arise within their premises any thing that becomes a nuisance to others or the public, are of course liable to inspection and, it may be, punishment; but an organized inspection of private houses by public officials would, even if practicable, be open to much abuse.

6. The Government observe that the numerical return of deaths in Madras in 1862 is already before them, embodied in the report of the Commissioner of Police; they hope, therefore, that Dr. Cornish's report for the same year will be forwarded as soon as the preparation of the accompanying tables and statements will permit.

7. The Government desire to express to Dr. Cornish their best acknowledgments for these complete and valuable statistics.

(True Extract.)

(Signed) J. D. SIM,

Secretary to Government.

REPORT

ON THE

CAUSES OF DEATH IN MADRAS,

FOR THE YEAR 1862.

1. The Public health throughout the year was in a most unsatisfactory state. Miasmatic diseases, especially cholera, small pox, and fevers prevailed to an unusual extent amongst all classes of the population. The total number of registered deaths was 14,731, a mortality considerably in excess of any of the preceding seven years during which registration has been maintained.

2. Of the 14,731 deaths in the Town of Madras no fewer than 9,260 are reported to have been due to miasmatic causes. In the years 1859, 1860, and 1861, the mean proportion of deaths from diseases of this nature was 7,027·3.

3. Some portions of the town however were more affected as regards the prevalence of diseases of the miasmatic class than others. If the rough census of the population lately obtained by the Officers of the Municipal Commission is to be regarded as trustworthy, then the ratios of mortality in the several Police districts of the town underwent the following remarkable variations.

Police	Proportion of deaths to 1,000 living. All causes.	Miasmatic diseases.
1st Division.....	18·58	11·53
2nd do.	49·97	32·26
3rd do.	27·11	15·93
4th do.	29·92	16·04
5th do.	53·88	34·32
6th do.	40·78	25·22
7th do.	21·51	15·77
In the whole of the Town	34·43	19·30

4. These ratios apply only to the mortality of the people living in the several police divisions, but in some of the sub-districts it was even more remarkable. Thus in "Choolay" in the sixth division, the population of which in the beginning of 1863 was said to be 4,266,

there occurred during the year 1862, four hundred and seven deaths, which gives a ratio of 95·40 per thousand to the living population.

5. The great variations in the mortality of different parts of the town go far to show that the causes determining the virulence of epidemic diseases are of a local, rather than of a general nature. The dirtiest and most crowded localities have as a rule been the most unhealthy. If "death loves a crowd," it is no less true that Poverty and Dirt are his chief allies, and that when these are associated with overcrowding, it is in such places that the Destroyer reaps his greatest harvest.

6. Epidemic Cholera prevailed more or less throughout the year. Its greatest ravages were confined to the 2nd, 5th, 6th, and 7th Police Divisions.

The European troops in the Fort Barracks escaped, but several cases occurred amongst the sick soldiers in the General Hospital at a time when the epidemic was severe in the adjoining district of John Peireras. There was less variation than usual in the *seasonal* prevalence of the disease. The mortality was high in the first two months of the year it began to decrease in March, and reached its minimum, in April. In May and June there was a temporary increase in the Cholera mortality, and in July a decrease. In August and September it rose again, but October and November were the months in which the greatest number of fatal cases occurred.

The lowest number of Cholera deaths was in April (102) and the highest in November (519). The total number for the whole year was 3,635, and the average monthly mortality 302·75.

7. It is not usual for Cholera to remain so constantly fixed to spot, but of Black Town (2nd Police Division) it may be said that from the time of the great epidemic in 1860 (when Sir Henry Ward died) up to the end of 1862, scarcely a week had passed without a considerable Cholera mortality. It increased and diminished now and again, but never ceased, and in the last year of its prevalence the deaths in the aggregate were more numerous than in any one of the seven preceding years. In the margin, the Cholera mortality for the whole town since 1855 is given for easy reference.

Deaths from Cholera.

1855	1956
1856	805
1857	1378
1858	1965
1859	1082
1860	2580
1861	2776
1862	3635

Since 1860, the Triplicane district has been much freer than usual

of the Cholera pestilence, and to whatever causes the improvement may be attributable, it is to be hoped that it is permanent.

8. The numbers of the various classes dying of Cholera are as follows :—

Europeans	...	...	28
East Indians	...	...	121
Hindoos...	...	...	2,869
Mahomedans	...	...	617

And the ratios of mortality from this disease according to the recent census of the population must have been :—

	Per 1000 living.
Europeans, and East Indians...	... 9·10
Hindoos, Pariahs and Native Christians...	8·25
Mahomedans	... 9·65

The census returns make no distinction between Europeans and East Indians, but it is probable that the Cholera mortality would be found heaviest in the latter class if separate population returns were procurable.

9. It is remarkable, considering how slightly the great Mahomedan quarter was affected in 1862, to find that the proportion of Cholera mortality in the Mussulman class was higher than that of Hindoos. The greater liability of these people to Cholera I have remarked upon before,* and it appears to indicate that the causes of the difference are to be looked for in the personal habits of the two classes, as well as in the localities they occupy.

* Reports for 1859, 1860.

10. Yet the influences of locality in predisposing persons to Cholera are very great. Taking for instance the general population of the several Police Divisions, and ascertaining the total number of registered Cholera deaths in each division, we obtain the following proportions :—

	Population.	Cholera deaths.	Proportion to 1,000 living.
1st Divison ...	58,264 ...	269 ...	4·61
2nd do. ...	90,740 ...	1,068 ...	11·76
3rd do. ...	81,166 ...	620 ...	7·63
4th do. ...	43,446 ...	152 ...	3·49
5th do. ...	41,715 ...	394 ...	9·44
6th do. ...	41,506 ...	458 ...	11·03
7th do. ...	70,934 ...	674 ...	9·50

11. These proportions are derived only from the returns of a single year, but they indicate sufficiently the districts which have suffered

most The over crowded and dirtiest neighbourhoods have not only furnished the most formidable of the cases, but a larger aggregate proportion of deaths

A thorough analysis of the Cholera death rate in the various parts of the Town will be deferred until the returns for a period of ten years can be obtained, for it is abundantly evident that the disease spreads very unequally in different years, in some seasons causing great mortality in Black Town, and sometimes spending its force in Vepery, Triplicane, or Royapooram It will scarcely be safe to draw any deductions beyond those of the most general character, until the mean death rate for Cholera and other diseases of the Miasmatic class for a series of years, of healthy and unhealthy seasons, can be obtained

12. The late census of the population taken by the Municipal Commissioners is not so useful for the elucidation of the health statistics of the Town as it might have been made if the sexes of "Children" and the total of all "Males" and "Females" in each district had been separately recorded The aggregate of the population as given by the Municipal Commissioners is probably not far short of the actual numbers, and in lieu of more accurate tables the present data will help to indicate with some approach to accuracy, the ratios of mortality in the various sub-divisions of the Town It is to be regretted also that separate returns of caste and race were not obtained on this occasion, and especially that the statistics of the European and East Indian population were lumped together

13 Small pox was unusually prevalent and fatal in the earlier months of 1862 The deaths from this disease from 1855 are shown in the margin. In the week ending 29th March, eighty-one deaths occurred from this loathsome malady. The disease prevailed at the same time very generally in some portions of the Madras, North Arcot, and Nellore districts, and at the end of 1862, it was raging in an epidemic form on the Western Coast. In Madras the epidemic began to decline in virulence after the end of March, and by the beginning of October it had almost disappeared

1855	852
1856	789
1857	243
1858	475
1859	473
1860	245
1861	655
1862	1033

14 The localities in which the small pox mortality has occurred are best seen in the following Table

	Deaths.	Proportion of deaths to 1,000 of population
1st Division.. ...	85	1·45
2nd do	368	4·05
3rd do.	179	2·20
4th do.	112	2·57
5th do.	109	2·61
6th do.	77	1·85
7th do.	103	1·45

It will be observed that there is no kind of correspondence between the ratios of small pox and cholera mortality in the same districts. The former disease is aggravated by overcrowding, as will be apparent from the large proportion of mortality in the dense population of the 2nd Division, but it seems to be less affected by surrounding insanitary conditions than most diseases of the Zymotic class. Small pox has a peculiar tendency to increase and decrease at regular periods of the year, at least this tendency has been noted in India and remarked upon by Dr. Leith of Bombay and myself. In the diagrams accompanying my Report for 1860, it was shown that the maximum prevalence of small pox in Madras occurred in the month of March, while at Bombay the maximum was attained one month later. The experience of the last year again illustrates the operations of the undiscovered law which regulates the periodical intensity of this disease.

15. But in addition to this tendency of the disease to become epidemic at a particular season of the year, it seems to run in a larger cycle, and to prevail in a particularly aggravated form at long intervals.

The period included in this larger cycle is not at present definitely known, though in Bombay it seems to occur every third year, but it is probable that the past year in Madras has been *the* one of unusual prevalence of small pox. At the present time it is worthy of note that small pox is unusually severe in Great Britain, notwithstanding all that has been done these many years past for the encouragement of vaccination. Also in Bombay in 1861 the mortality from small pox was unusually high.

16. In regard to small pox, it will be found as a rule that the class of persons who have been subjected to the prophylactic of vaccination in infancy have the lowest mortality. But in the aggravated form of the pestilence, as it occurs now and again, the disease seems to seek out and attack all those who have been imperfectly vaccinated, as well as those who have undergone no preventive treatment, nay even

those who bear marks of successful vaccination are not always exempted, though the malady but rarely proves fatal in such cases.

The following are the proportions of small pox deaths to the population of the several classes. East Indians and Europeans are included under the same heading in the census returns.

	Small Pox deaths		Ratio per 1,000 living.
Europeans and East Indians...	39	.....	2 38
Hindoos and Native Christians	897	.....	2·58
Mahomedans.....	97	.....	1·51

17. The remarkable thing in these proportions is that the Mussulman community appear to be better protected by vaccination than any other class, except perhaps Europeans. The large proportion of small pox cases in the first class arises principally from the prevalence of the disorder amongst East Indians. *Thirty-four* East Indians, and *five* Europeans died of small pox. The exact numbers of the population of these classes cannot be obtained from the census papers; but if the small pox mortality obtained in both classes at the same ratio, there would be seven Eurasians to one European living in the town, a proportion which certainly does not exist. To arrive at clearer views on this subject, it will be necessary to calculate the proportion of small pox mortality to the whole number of deaths in each class; the results are as follows :—

Proportion of Small-pox to the Total mortality.

Europeans	3 20	per cent.
East Indians	8 17	do
Hindoos...	7 35	do
Mahomedans	4·93	do.

It will thus be evident that the lowest rate of mortality occurred in the class, which is best protected by vaccination, *i. e.* Europeans. The large mortality of East Indians from small pox, betrays, it is to be feared, great neglect of the prophylactic of vaccination.

Of the five fatal small-pox cases amongst Europeans all occurred in young children, but amongst other classes of the community the epimedic was fatal to adults as well as children.

18. Measles was rather more fatal than usual, 27 deaths were due to this cause.

19. The deaths from other diseases of the Miasmatic class, and especially fevers, diarrhœa, and dysentery, have been numerous but not greatly in excess of the average of former years.

20. The large number of 1,081 young children are registered as having died of convulsions; of these 1,070 were under one year of age. I have noticed in a previous report* that the miasmata which prevail in the unhealthy years in Madras affect tender infants chiefly by exerting their poisonous influences upon the nervous centres, at least that such appears to me the most reasonable explanation of the coincidence of a large mortality from convulsions in the seasons when miasmatic diseases are rife.

For 1861.

21. The deaths from violence have been fewer in 1860 than in either of the three preceding years. Of the 115 cases recorded under this head 61 were the result of drowning, either accidental or suicidal. The number of Coroner's inquests during the year was 166, but some of these were held in cases of death from natural causes. One death from "poison" is recorded, and four from "snake bite." With these exceptions there is nothing particularly worthy of remark in connection with the deaths from violence or accident.

22 I append a valuable Table of the principal Meteorological Phenomena of the year compared with the mean average of the twenty years 1841—1860, kindly drawn up by Mr. Pogson, Government Astronomer. It will be observed that the Barometric readings of the year were very slightly below the average; the mean temperature as ascertained by the dry bulb thermometer 0·7 of a degree higher, and of the wet bulb 0·9. The mean reading of the dew point was 1·1 degree higher, and the degree of humidity 1· above the average.

With regard to the force and direction of the wind, these have been carefully recorded for 1862, but the averages of the twenty years are wanting for comparison.

The entire rain fall for the year was only 38·18 inches, or 12·57 inches less than the average. Rain fell on 96 days in the year.

The average per-centage of cloud in the atmosphere was 1 below the average.

23. A systematic analysis of drinking water from the principal sources of supply in the town of Madras has never yet been undertaken. I have every reason to hope that this important subject will engage the attention of Dr. Wyndowe, the officer appointed to succeed Mr. Mayer in the office of Chemical Professor and Examiner. Mr

Modeen Sheriff, the Native Surgeon of Triplicane, has at my suggestion undertaken a comparative examination of the degree of impurity from organic matters in numerous specimens of well and tank water of Madras.

The experiments, I have reason to know, have been most carefully conducted, and the results, although they cannot be regarded as of the same value as a *quantitative* analysis of each specimen of water would be, are sufficiently accurate to show that much of the water used for drinking purposes by the people of Madras contains a dangerous proportion of organic matter in solution or suspension. I append in a tabular form the results of Mr. Modeen Sheriff's experiments.

24. A report on the causes affecting public health during the year would scarcely be complete, without mention of the completion of the Trevelyan water works and the commencement of operations for flushing the drains of Black Town. From the faulty construction of the street drains and the rotten condition of the brickwork, it is evident that some of the salt water of the Canal which is pumped into the reservoir to flush the drains, instead of running out to sea with the sewage, finds its way into the soil through the defective masonry of the drains, and already, from this or some other cause, the residents of Black Town are beginning to complain that their "sweet water" wells are becoming contaminated by salts. There seems also some reason for supposing that the water conveyed in pipes from the seven wells to the Fort is contaminated at some point along the course of its flow.

25. During the course of 1862 after inspecting with Major Bell, President of the Municipal Commission, the flushing operations in connection with the water works, I suggested to that officer that until a more perfect material than brick and chunam for street drains could be devised the process of flushing was not likely to be attended by satisfactory results. A considerable portion of the water used must inevitably sink into the soil, carrying with it fluid sewage, as all the brick and chunam street drains after a few years use become more or less porous to fluids.

As there are some 80 miles of open street drains in Madras, Major Bell was of opinion that the cost of cut granite (the best of all materials) would be so great as to preclude the recommendation* of the Principal Inspector General for its use being carried into effect.

---

* Letter No. $\frac{72}{159}$ A, 27th August 1862.

26. After giving some little attention to the matter I came to the conclusion that the laterite which abounds close to Madras would answer the purpose equally as well as granite, and from its peculiar property of being easily cut into any shape when quarried in a soft state the cost of making good street drains would probably be very much reduced. I suggested slabs 18 inches in length cut in the centre as shown in the section given in the margin, laid end to end and cemented with some material destitute of lime.* The cutting for small streets need not be more than 6 inches in depth by 9 in width, such slabs could probably be cut and laid for about 1½ Rupees a yard. The feasibility of this proposal was admitted by the Municipal Commissioners, who I believe directed that a certain number of yards of street drains should be laid with laterite as an experimental measure

The reason which induced me to recommend a trial of laterite for street drains were these ·

1 The stone after once being hardened by exposure to air acquires a glazed surface which is indestructible by all ordinary atmospheric agencies, salt, or fresh water . Near the Red hills lake there are the remains of an ancient burial place, in which all the cairns are built of laterite, and although these have been exposed to the sun and wind and rain for perhaps a period of three thousand years or more, some of the slabs still retain the marks of the cutting instrument with which they were shaped as plainly as when fresh from the quarry.

2. The comparative cheapness of the material and the facility of working it, seemed in addition to its durable nature, the best recommendations in its favor. Laterite blocks many years ago were much used in Madras for building The old houses of Saint Thomé have a good deal of laterite in them. The Mylapoor tank is faced with this material, and in fact most of the old substantial works are built of it. The great object of preventing the percolation of sewage into the soil will, I think, be better attained by using this material than by the present brick and chunam drains.

W R CORNISH, *Assistant Surgeon,*
Secy. Principal Inspector General
Medical Department.

25*th July*, 1863.

* The contents of sewers are very destructive to chunam, and if possible its use should be avoided in the jointings. .

APPENDIX B.

Table showing the extent to which each of the waters examined is made use of, and by whom used; arranged according to the Police Divisions of the Madras Presidency.

No. of the specimen.	Proportion of organic matter—taking distilled water as a standard, determined by the permanganate test.	Insoluble impurities—grains in an imperial pint.	Name or place of the well or tank.	To what extent and by whom used.
			No 1. Police Division.	
17	2	¾	Well in the compound of the Light House near the Beach.	By almost all Native inhabitants of Chetty's, Armenian, and other streets in Black Town on the southern side of this Division.
			No 2. Police Division.	
9	0	0	One of the seven wells supplying water to the Fort, &c.	By all Europeans living in the Fort and their Native servants; by all Europeans, East Indians and Natives that have to stop in the Fort during the day; and by some Europeans and East Indians, &c. in Black Town. His Excellency the Governor's household and some gentlemen living at a great distance from the Fort also drink this water.
18	1¼	¼	Well in the corner of the Esplanade opposite to the Thieving Bazar.	By all inhabitants living around and near the Thieving Bazar, and by many of those in John Peirarras.
19	¼	0	Well in the Esplanade opposite to the Memorial Hall.	By many of the residents in John Peirarras and some from other parts of this division. This water is slightly brackish.
27	1	⅛	Well in Black Town in a compound now occupied by a Cotton Factory.	By all classes of people in the Northern side of the 1st Police Division in Black Town, except by some Europeans and East Indians.
33	0	0	Well in Black Town near Elephant's gate.	By nearly the whole population on the northern half of this division in Black Town.
			No. 3. Police Division	
5	4	2¼	Tank in Chepauk Palace.....	By about $\frac{3}{16}$ of the population of Triplicane, chiefly of the middle and lower class. This tank is less resorted to by people at present than it was some years ago
6	2	½	Well near the Tank in Chepauk Palace.	By some inhabitants of Black Town.
10	1	⅛	Well in Burying and burning ground of Hindoos near the Beach on the side of the Ice House.	By about $\frac{1}{16}$ of the population of Triplicane consisting wholly of Brahmins and Hindoos.
25	0	0	Well in Halls' garden between Royapettah and the Thousand Lights.	By all those living near the well, by many inhabitants of the Thousand Lights and also by some rich people of Triplicane and Royapettah.
34	2	½	Tank in Governor's garden	By a few of the inhabitants of Triplicane and Nursingapoorum.
			No. 4. Police Division.	
1	2	¼	Tank in Royapettah behind the Police Court (in Heeseeamool Moolk's garden).	By almost all the inhabitants of Meer Sahib's pettah by about ¼ of the population of Royapettah and $\frac{6}{16}$ of that of Triplicane, chiefly of the low and middle class

No. of the specimen.	Proportion of organic matter—taking distilled water as a standard, determined by the permanganate test	Insoluble impurities—grains in an imperial pint.	Name or place of the well or tank.	To what extent and by whom used.
2	3	¾	Tank in Royapettah in Sirdar Jung's house opposite to the Civil Dispensary.	By some inhabitants of Royapettah
3	5	2⅜	Elephant tank in Meer Sahib's pettah	By some of the lowest class of people in Meer Sahib's pettah and Triplicane.
4	2	½	Well near the Elephant tank . .	Do do do.
7	0	0	Well in Royapettah on the side of the main road leading to the Sea (chuddle or Amma Covil's well)	By about ½ of the population of Royapettah, chiefly of the high and middle class and by some rich people in Triplicane.
8	3¼	2	Tank in Pater's garden in front of the Madras Club . .	By about ¼ of the population of Triplicane chiefly of the low and middle class
11	1	¼	Well in Mylapoor on the side of the largest tank of that place.	By almost all the inhabitants of Mylapoor, except Brahmins, who use the water of another well near this one and on the side of the same tank, the water of the well used by Brahmins is not examined, as it is exactly the same in appearance and taste, and will probably contain the same degree of organic matter as No 11.
12	1	⅛	Well in a garden on the northern side of the Adyar bridge (Naseem Baug)	By some noblemen in Triplicane, including Prince Azeemjah Bahadoor and those Natives living near the garden.
30	2	¼	Well in Royapettah in a Moonshee's garden	By some of those living near the well
32	2	⅓	Well in Kistnapettah	By almost all the inhabitants of Kistnapettah
35	1	¼	Well in Thennapettah in a compound near the Company's garden	By some of those living in Thennapettah
36	½	¼	Well in Pater's garden in front of the Madras Club near the tank	By about $\frac{1}{10}$ of the population of Triplicane, chiefly of the middle class
42	0	0	Well in Sullivan's garden near Mylapoor in the compound of Revd Mr Percival	By some European gentlemen residing in the 4th District including their servants
43	0	0	Well in Luz near Mylapoor ...	By all those living in Luz, and by many Europeans and East Indians at Saint Thomé
			No 5 Police Division.	
13	¼	⅛	Well in Nungumbaukum in His Excellency the Commander-in-Chief's Garden	By some European gentlemen living in Nungumbaukum including their servants.
14	0	0	Well in Egmore or Ellumboor on the side of the Poonamallee road	By many European gentlemen from all parts of the Presidency, by all the inhabitants of Egmore, by all the high and middle class of people (including European and East Indians) of Kilpauk, Pursewalkum, Vepery and New Town, and also by few of the inhabitants of Nursingapoorum and Chintadripettah
20	¼	⅛	Well in the Esplanade opposite to the Body Guard.	By some inhabitants of Nursingapooram and Chintadripettah
24	2	½	Tank on Mount Road in McNeale's garden on Moorad Beg	By many people living along the Mount Road and in Chintadripettah and Munnarswamy Covil, and also by a few of those residing in Triplicane.
28	1	⅛	Well in Poodpettah or Begum Bazar on the side of the Marshall's road	By almost all the inhabitants of Poodoopettah and by many of those of Comalieswaram pettah.
37	2	½	Tank in Lying-in-Hospital...	By about ½ of the population of Chintadripettah, including all classes and by the patients of the Hospital

No of the specimen	Proportion of organic matter —taking distilled water as a standard, determined by the permanganate test	Insoluble impurities— grains in an imperial pint	Name or place of the well or tank	To what extent and by whom used
40	3	½	Well in Nungumbaukum on the northern side of the large lake	By many Natives living in Nungumbaukum, and by all those living near the well.
44	0	0	Well in Nungumbaukum in Coamtys garden near Dr Sherman's quarters	By some European gentlemen residing in Nungumbaukum and Thennapettah including their servants
			No 6 Police Division	
15	1¼	¼	Well in Lunatic Asylum . . .	By the inmates of the Asylum and by some inhabitants of its vicinity
16	4	1	Tank in Peramboor	By large numbers of inhabitants of Peramboor including the Sepoys and followers of Native Regiments
22	4¼	1⅙	Tank in the Regimental Lines in New Town or Vepery	By all poor inhabitants of New Town and Vepery including the Sepoys and followers of the Regiment
45	½	⅛	Well in Vasarapaudy	By all the inhabitants of that place
			No 7 Police Division	
26	0	0	Well in Black Town in Monegar Choultry	By the inmates of the Institution
47	¼	⅛	Well in Cashmeeloo	By all the inhabitants of that place
48	½	⅛	Well in Royapooram	By all the people living in Royapooram
49	1	⅛	Well in Washerman's pettah	By all the inhabitants of that place
50	1	⅛	Well in Tondiarpettah	By all the inhabitants of that place
			Beyond the limits of the Police Divisions of the Presidency	
21	0	0	Well in Adyar beyond the bridge	By many European gentlemen including their servants in Adyar
23	0	0	Well in Codumpockum in Canthib's garden	By many inhabitants of that place
29	¼	⅛	Well in Sydapet in a compound near the Collector's Cutcherry	By many of those living near the well and by some rich Mahomedans of Triplicane
31	2	½	Sydapet River	By some of those near the River
38	0	0	Well in Saint Thomas Mount behind the Soldier's Bazar	By many Europeans and Natives of Saint Thomas Mount
39	¼	0	Well in Saint Thomas Mount Ghurruj Chetty's well	By a large portion of Natives of that place
41	0	0	Well in Sydapet beyond the river	By all those near the well and by a few rich Mahomedans of Triplicane
46	¼	⅛	Well in Peramboor a little beyond the Railway Station	By all those near the well and by some from Peramboor.

N. B.—It will be seen from the preceding Tables that of the 50 specimens of water examined no less than 13 were as pure as distilled water as regards organic matter and insoluble impurity, and about 6 more were nearly so. The water of tanks is invariably more impure than that of wells; and of all the tanks in the Tables, the Elephant tank contains the worst water. There are many more tanks in Triplicane, Black Town, Mylapoor, Vepery, &c., whose water is much worse than that of the Elephant tank, but as their water is not made use of for drinking, I have not examined them. Some of these tanks however, are in use by Brahmins for bathing and washing clothes.

In some places there are many wells or tanks near each other, or in the same neighbourhood, as is the case with Nos. 9 and 27, in such cases the water of only one or two that are mostly in use by the people was selected for examination, the water of others being generally considered to be equal to that of any of the wells or tanks (as the case may be) in the above Tables that may be situated nearest to them.

1st Division.—The inhabitants of the 1st Police Division, except some Europeans and East Indians, make use of rather impure water from Nos. 17 and 27, but those living in the Fort (which is included in this Division) are supplied with very pure water from No. 9.

2nd Division.—With the exception of those living near the Thieving Bazar, all other inhabitants of this Division obtain good water chiefly from Nos. 19 and 33.

3rd Division.—Of all the inhabitants of the Presidency, those of the 3rd Police Division generally make use of the worst water; from Nos. 1, 5, 8, 6, 10, 36—none of which contains pure water. There is no well of pure water in this Division except No. 25, and this is so far from the main portion of the population that it is only resorted to by a very few in comparison to their great number.

4th Division.—The whole Native inhabitants of Mylapoor, Meer Sahib's pettah, Kistnapettah and many of those of Royapettah make use of bad water; from Nos. 11, 32, 4, 3 and 1. Although there are many wells of good water in this Division, such as Nos. 7, 4, 2 and 43, but with the exception of the first they are situated far away from the villages and are not therefore resorted to by many people.

5th Division.—The most populous villages in this Division, Chintadripettah and Nursingpoorum are not able to procure good water, but generally obtain impure water from Nos. 37 and 24. The rest of the inhabitants of this Division get very good water from No. 14, &c.

6th Division.—With the exception of those inhabitants of New Town and Vepery that are not able to buy water for themselves, all others in this Division are supplied with very good water from No. 14, &c.

7th Division.—In this Division the inhabitants are in possession of many wells, generally of pretty good water.

Beyond the limits of the Police Divisions—pure water is procurable abundantly beyond the limits of Jurisdiction in St. Thomas' Mount, Adyar, Codumpauk, and Sydapettah, &c.

MADRAS,
10th *June* 1863.

(Signed) MOODEEN SHERIFF.

PUBLIC DEPARTMENT.

PROCEEDINGS OF THE MADRAS GOVERNMENT.

Read the following Report on the causes of death in Madras for the year 1862:—

(Dated 25th July 1863.)

ORDER THEREON, 8th March 1864, No. 287.

The year 1862, to which the foregoing report refers, was the third successive year of unfavorable seasons at Madras and was marked, as might have been expected, by a large increase in the mortality from Miasmatic diseases, on the rise and fall in which the total number of deaths so greatly depends. In 1860, the monsoon rains failed almost entirely; in 1861 there were only 36, and in 1860 only 38 inches of rain instead of 51, which has been considered the average rain-fall in Madras. The succession of bad seasons therefore seems to have more than counterbalanced the advantages of the slight increase in the fall of rain, and an only ordinarily high temperature, the whole mortality in Madras during 1862 having been considerably higher than any yet registered. In all three years Cholera and other Miasmatic diseases prevailed from time to time with unusual virulence, and it is remarked by Doctor Cornish that in Black Town it may be said that, since the first great epidemic in 1860, when Sir Henry Ward died, up to the end of 1862, scarcely a week passed without a considerable Cholera mortality. It increased and diminished now and again but never ceased, and in the last year of its prevalence the deaths in the aggregate were more numerous than in any one of the seven preceding years during which deaths have been registered.

2. The mortality in the whole town from both Cholera and Small-pox was greater during 1862 than it has ever been, the number of deaths from these causes being no less than 3,635 and 1,033, against 2,776 and 655 in 1861, itself an exceptionally unhealthy year, and showing a mortality from these diseases considerably above the average. The deaths registered, as caused by other diseases of the Miasmatic class, though numerous and making the total number of deaths from this class of diseases no less than 9,260 against a mean proportion of 7,027 in the three previous years, were not greatly above the average. A large portion of the deaths of infants registered as from convulsions,

and which in 1862 reached the number of 1,081, may, however, as noticed in a former report, be more truly ascribed to Miasmatic causes. The real number of deaths owing to these causes will therefore be probably not far short of 10,000.

3. It is satisfactory to know that the experience of a favorable season, since 1862, has shown that the great increase in the mortality of Madras during the last few years may be correctly ascribed to seasons of great drought and prolonged high temperature; for the steady rise in the number of deaths, even after the registration was deservedly thought to be fairly efficient, leaves no room to question its reality.

4. The drawing of any deductions beyond those of the most general character from the returns as yet obtained, is of course still unsafe, but the death rate in the 2nd Police Division shows how greatly the rate of mortality depends on local influences, and how urgent is the necessity for the enforcement of sanitary measures in that part of Madras. In 1862 the proportion of deaths from both Cholera and Small-pox was higher there than in any other part of Madras, while from the denseness of its population the actual number of deaths was beyond comparison greater.

5. The Government regret to learn, from the remarks made by Doctor Cornish in paragraph 17, that Vaccination is still apparently much neglected by the East Indians of the Presidency Town.

6. The table of the principal Meteorological Phenomena of the year, prepared by Mr. Pogson, the Government Astronomer, is a valuable addition to the present report.

7. A systematic analysis of the water used for drinking purposes by the people of Madras is very desirable. Native Surgeon Moideen Sheriff's experiments, which are stated to have been made with much care, seem to show that much of the water now used contains a dangerous proportion of organic matter.

8. The Government remark that this report, though dated on the 25th July last, only reached the Government Office on the 17th of December. They will expect the report for the past year to be submitted at a much earlier date.

(True Extract.)

A. J. ARBUTHNOT,

Chief Secretary.

TENTH ANNUAL REPORT ON THE CAUSES OF DEATH IN MADRAS, FOR 1864.

THE year 1864 has been a remarkably healthy season in the Presidency town of Madras. Cholera and small-pox, the two epidemics that cause the greatest fluctuations in the death-rates of Indian towns, have been uncommon, especially during the latter half of the year. The total number of deaths registered was 10,409; of these only 574 were due to cholera, and 173 to small-pox. The mortality from fevers and bowel complaints was also below the average. The immunity from fatal disease that has characterized the year 1864, in our chief city, has not been observed elsewhere. In many parts of the Presidency, cholera has been rife; in others, malarious fevers have been unusually prevalent, and in Kurnool and Coimbatore especially the mortality of horned cattle from a form of "murrain" has been unusually high.

2. The following table shows the total number of registered deaths, and the principal miasmatic diseases for the past ten years. It will be seen that the last year of the series contrasts very favorably with those immediately preceding it:—

Total Mortality.		From Cholera	Small pox.	Diarrhœa and Dysentery.	Fevers.
1855	10,627	1,956	852	1,574	1,729
1856	8,433	805	789	1,137	1,510
1857	6,968	1,378	243	835	764
1858	10,148	1,965	475	1,032	1,896
1859	10,292	1,082	473	1,297	2,378
1860	13,498	2,580	245	2,338	2,459
1861	13,370	2,776	655	2,334	2,169
1862	14,731	3,635	1,033	2,203	2,235
1863	11,858	1,684	112	2,154	2,117
1864	10,409	574	173	1,996	2,083
Mean of ten years.	11,033·4	1,843·5	505·0	1,690·0	1,934·0

3. The proportion of deaths from "Miasmatic" diseases has been comparatively very low during the past year. It is not so easy to explain why it should have been so. If an improved water supply had been provided, and large drainage works executed, it would have been but fair to assume that some portion of the reduced death-rate was due to these important sanitary measures; but as the water supply and drainage projects exist at the present time only on paper, a rational "explanation" of the salubrity of the town is wanting.

4. Without attempting an hypothesis of my own to account for the extraordinary healthiness of the population, I prefer to chronicle the bare fact that the year 1864 has been remarkable for shewing a lower death-rate from cholera, than any one of the nine years preceding it. What the cholera mortality may have been previous to 1855, we have no means of ascertaining; but there is reason for doubting (judging by the Presidency Hospital Returns) whether the deaths from cholera have ever been fewer than in the past year.

5. Cholera prevailed chiefly in the first and third quarters of the year. In the first quarter, the East Indian community living in a circumscribed locality in New Town suffered severely. The disease had been introduced to them from the camp of H. M.'s 74th Highlanders, then quartered on the Race Course at Guindy. The account of the mode of introduction is given in my Quarterly Report as follows:—

"It seems that a Hospital Cooly of H.M.'s 74th Highlanders (that "Corps having at the time cholera cases in camp) was in the habit of "coming home of nights to his hut in New Town. A servant to the "Quarter Master Serjeant of 2nd Regiment N. I. lived in the same "hut or house with this Cooly, and therefore the chain of communica-"tion between the cholera camp and the house in New Town where "the first case occurred, may be regarded as complete. A child of the "Quarter Master Serjeant was taken ill on the night of the 27th, "another on the 28th, and both died. On the latter date the wife and "child of the Serjeant Major of the Regiment, living close by, were "attacked and died, and from this time the other cases followed in "rapid succession. It seems that the servant boy had come to the "Quarter Master Serjeant's house late at night on the 27th, and that "almost immediately after, the first child that was attacked began to "sicken"

6. Curiously enough another instance of the communicable nature

of the cholera poison was afforded during the prevalence of the disease in the camp of H.M.'s 74th Highlanders. It is full of warning and instruction. The particulars are extracted from the Stational Report of the Zillah Surgeon of Chingleput:—

"Cholera first made its appearance on the 24th February 1864. "Two bandymen belonging to this place, who were engaged in transport-"ing tents of the 74th Highlanders from Guindy to Palaveram, when "the Regiment shifted its quarters in consequence of the out break of "cholera, in their ignorance appropriating to their own use the *straw* "*spread in the tents* of the cholera patients.

"No sooner had they deposited their loads and turned homewards, "than they were seized by the disease, and both fell victims to it the "day after their arrival here. The disease now spread, and several "cases were reported to have occurred in the town."

7. In connection with the immunity from cholera enjoyed by the greater part of the Presidency town during the last year, may be mentioned that the great festival at Conjeveram in May passed off without the disease showing itself amongst the pilgrims. Cholera, I believe, has been not unfrequently introduced into the Presidency town by persons returning from the festivals held at Conjeveram, Tripetty, Trivellore, and other celebrated Hindoo temples in the neighbourhood. In the month of May 1864, the Sanitary Commission obtained the sanction of Government to incur some trifling expenditure in the conservancy of Conjeveram during the festival period. No cholera appeared at this season, but indeed the whole district was remarkably free of the epidemic throughout the year, so that it cannot be said that mere sanitary precautions on this occasion were the means of keeping away cholera. Nevertheless the measure was a prudent one, and should never be neglected in future.

8. In the report for the year 1860 I took occasion to show that the most destructive pestilences of modern times could generally be traced to the assemblage of pilgrims at the various shrines. In the year in question I instanced the diffusion of cholera throughout the Central Provinces, by means of the pilgrims visiting the temples at Mahadeo.

During the past and present year of 1865, two fearful epidemics have taken their origin from the same spot. The troops at Nagpore have suffered on both occasions, the high road between the terminus

of the railway and Nagpore has been literally a valley of death for months together. Officers, their families, and native travellers innumerable, have fallen victims in attempting to pass it. In another direction cholera has passed down the valleys of the rivers leading into the Godavery.

It has attacked the coolies employed on the important public work in connection with that river, so that the whole camp became for a time demoralized. At the station of Doomagoodien, the deaths, up to date, had numbered 328. Many coolies had deserted to their homes, carrying disease, it is to be feared, in their track.

9. While I write I hear of another outbreak of cholera amongst the pilgrims at Juggernaut;—already the disease has spread to several towns and villages in the Northern Division.

10. The completion of the various lines of railway communication will no doubt be advantageous, so far as diminishing the risk to travellers. They will be spared the fatigue and privations inseparable from long pilgrimages, by adopting the new means of travelling. On the other hand it must not be forgotten that the facilities of travel which the railway offers, expose the populations of towns at a considerable distance from the pilgrims' shrine, to the risk of cholera infection. Instances of cholera having been conveyed a long distance by means of railway passengers have not been infrequent of late.

During the year under report I have reason to believe that cholera was introduced into Cochin by a person who contracted it at or near Coimbatore; and, on the second occasion, by the crew of a native vessel visiting the Port. More recently still, there is evidence that a Railway Guard contracting cholera at Beypore, was the means of diffusing the pestilence in an epidemic form in the neighbourhood of the Railway station at Coimbatore.

11. It may be quite true that the introduction of the cholera poison into a crowded population is a matter of no great moment, so long as the hygienic condition of the population and their homes is all that is desired, and that the great object should be to strive to induce the various communities to put themselves in the best sanitary condition possible; but, nevertheless, there will always be great risk and danger of cholera breaking out in a virulent form, if we neglect to battle with the disease in its strongholds.

12. The mass of evidence already accumulated shows that the assemblage of large bodies of persons at the various temples year after year, without any provision whatever being made for the health and comfort of the pilgrims, is the most frequent source of cholera outbreaks; while the rapid dispersion of the pilgrims on the appearance of pestilence amongst them, favors the spread of the poison, which undoubtedly tends to run along the ordinary channels of human intercourse.

13. The difficulty of meeting the evil by direct legislation has, no doubt, occurred to the Members of Government. As to the best means of enforcing sanitary obligations upon the communities which have the care of religious houses, this is scarcely the place to speak. My duty seems to be to state the fact, that the annual festivals at the various religious shrines in this country tend more to the perpetuation and yearly diffusion of cholera than anything else I am acquainted with. The more the particulars of each epidemic are enquired into, the clearer it is seen that the congregation of pilgrims is an evil of the first magnitude, and I would add that, until something is done to mitigate the dangers attending their assemblage, our Sanitary care of Military Cantonments will be powerless to lessen the present risks to troops serving in India.

14. The town of Madras is no better situated for resisting cholera invasion now than it was five years ago. The present immunity must be regarded as exceptional. The place, I admit, has been, on the whole, healthy for a period of nearly two years; but it has been so, not by reason of improvements in drainage and water supply, but in defiance of all the ordinary sanitary laws that we are acquainted with. Philosophers of the school advocating the doctrine of the "wholesomeness of stinks" may in future point to Madras as a great example of the soundness of their theory. A scanty supply of good water, bad drainage, foul odours in abundance, and imperfect conservancy, have been the marked features of the past year, as of a good many preceding it, and yet the population have been fairly healthy. In making this statement I do not depend merely upon the information gathered from the Mortuary Register. The Medical Officers practising at the Presidency all bear testimony to the infrequency of epidemic disease, and to the freedom of the people from serious sickness.

15. The fact, such as it is, I am afraid is likely to have the effect

of lulling us into a sense of false security, and to bring about a feeling of indifference as to the prosecution of expensive works mainly for the improvement of the hygienic condition of the people. These works are, I believe, more urgently needed now than they have ever been. The water-bearing strata of Madras are yielding a supply less and less pure. The surface and deep drainage of the town is in a most unsatisfactory condition. The next cholera epidemic, when it comes, is sure to test the weak points in the sanitary condition of the town. We shall find—probably, as of old, that filth and overcrowding will determine the violence of the pestilence, and that the districts worst off in these respects will be the ones to suffer most.

16. The small number of casualties in Madras from small-pox during the last two years induce me to think that the appointment of a Special Superintendent of Vaccination has been so far useful that vaccination, where it is performed, is now well done, and, consequently, fewer people are liable to take small-pox. The number of unvaccinated must still be great. The births in Madras cannot be much short of 12,000 a year. Of children under one year of age, only 3,330 were vaccinated in 1864.

17. In the report for 1863, I stated my intention to submit the results of ten years' registration of deaths in Madras, with such observations as the figures appeared to demand. The tables are now in course of completion, and in a short time I hope to be able to submit them in a separate communication to Government.

Mr. Pogson's Annual Meteorological table is annexed (with that gentleman's notes on the more noticeable phenomena of the past year).

Madras Half-monthly and Annual Meteorological Results for the year 1864, *compared with the average of the twenty years,* 1841—1860.

NOTES.—Throughout the year 1864 the readings of the Barometer remained above the average: the mean temperature was 0°·4 above, while the wet bulb was 0·3° below the twenty year average, making the percentage of Humidity also 2 less than usual.

The force of the wind as represented by its daily velocity in miles, was 19 miles per day in excess of a four years' average. The mean direction for the whole year was S. E. by E. or two points eastward of the average direction for twenty years. The annual daily statical resultant velocity did not, however,

FORT ST. GEORGE, 15*th June* 1865.

W. R. CORNISH,
Secy. Principal Inspector Genl. Medical Department.

exceed 70 miles, owing to the counteracting effects of opposite winds; and the calculated direction was 8 by E.

The rainfall for the whole year was only 93 per cent. of what it should have been, notwithstanding its being helped out by a remarkable downpour on November 18th, when 9·35 inches fell in a few hours; a quantity only exceeded on five days since the year 1822. Rain fell on 93 days during the year The hottest day in the year was June 1st, when the Thermometer reached 101° 8 in the shade. On the morning of January 28th it fell as low as 60° ·6
